PHYSICAL THERAPY IN DERMATOLOGY: A BRIEF GENERAL OUTLINE

CHAIRMAN'S ADDRESS

GEORGE M. MACKEE, M.D.
NEW YORK

The specialty of dermatology has grown increasingly comprehensive during the past three decades. In addition to the clinical skill peculiar to dermatology, the successful practice of the specialty requires a knowledge of the basic medical sciences, practical experience in general medicine and surgery and clinical laboratory methods and a training in physical therapy. Ability to do experimental and laboratory research and ability to apply to clinical problems the various diagnostic and therapeutic methods make the thoroughly trained modern dermatologist more self-reliant than were his predecessors.

Physical therapy has been an important factor in the evolution of practical dermatology. It has helped to broaden the field. For many years physical therapy enabled the dermatologist to obtain therapeutic results that could be obtained in no other way. This statement is also applicable to modern dermatology but to a lesser degree. Increased knowledge relative to the etiology and therapeutic requirements of many dermatoses has made it possible to lean less heavily on the various physical therapeutic methods. This fact is evidence of progress, and with such progress the specialty becomes more comprehensive. Certain aspects of dermatologic physical therapy will become less important in the future, but it seems safe to predict that physical therapy will continue to be of great value in dermatologic practice into the remote future.

While the various physical therapeutic methods are used with skill and excellent judgment by the majority of American dermatologists, they are injudiciously and improperly employed by some. Such conduct is inimical to the best interests of both dermatology and physical therapy. Physicians who are discrediting physical therapy fall into several classes. Some treat cutaneous lesions without much knowledge of either dermatology or physical therapy. Others have received adequate training in physical therapy, but treat cutaneous diseases without dermatologic supervision. The efforts of such physicians frequently produce undesirable results, and from such sources emanate inaccurate and misleading statements. Among the dermatologists are those who attempt physical therapy without adequate training in its application. Naturally the best results cannot be obtained in this manner. There are others who have acquired technical skill but whose training in dermatology and general medicine has not been sufficient for therapeutic resourcefulness. These physicians are likely to use physical therapy as a path of least resistance to the exclusion of conventional therapy. Finally, there are those who have both technical skill and general dermatologic ability, but, being incapable of guidance, they acquire the faculty of accurate judgment only by experience.

Many of these faults can be remedied in time. In the past it has been difficult for dermatologists to acquire suitable training in physical therapy. In many instances their elementary knowledge was obtained from manufacturers of physical therapy apparatus, itinerant lecturers who were not sponsored by altruistic medical bodies, and books that failed to receive recognition by outstanding members of the two specialties.

Many physicians who specialized in general physical therapy in the past were not fitted by education or temperament for the task of placing the specialty on a sound scientific basis. The various physical therapeutic methods were injuriously exploited by these physicians and by manufacturers of physical therapy apparatus. The specialty was in disrepute. It did not offer an attractive field for young physicians of scientific mind. There were, nevertheless, in this field many scientific workers whose accomplishments were epochal, but such advances were not universally recognized until the World War, when physical therapy received a great impetus. Since then the scientific advancement of the specialty has been rapid, and there is less tendency to glance askance at it.

During the past few years several practical steps have been taken for the purpose of enhancing the standing of the specialty, and to safeguard the medical and lay public against undesirable exploitation. The Council on Physical Therapy of the American Medical Association was formed six years ago. This council is gradually separating the good from the bad in physical therapy. Through its educational articles it has provided the medical profession with reliable information regarding physics, biology, chemistry and physiology, as related to physical therapy. These articles also contain an evaluation of clinical results. They have been published in book form by the American Medical Association and are now available to all physicians. The Council on Physical Therapy functions in much the same manner as does its older brother, the Council on Pharmacy and Chemistry. It carefully considers all physical therapy devices submitted to it. Acceptance or rejection is based not only on the usefulness and quality of the device, but on the character of the advertising propaganda. In time both the manufacturer and the physician will realize that approval of a device by the Council means protection for both.

Read before the Section on Dermatology and Syphilology at the Eighty-Third Annual Session of the American Medical Association, New Orleans, May 11, 1932.

A comprehensive, authoritative, much-needed practical work on physical therapy for practitioners of general medicine has been prepared and is now in press. While this work is not officially sponsored by the Council, it was inspired by individual members of the Council, most of whom are independent contributors.

American dermatologists have just created an American Board of Dermatology and Syphilology, patterned after similar boards that have done so much for ophthalmology, gynecology and other specialties. The duty of this board will be to certify to the ability, probity and ethics of dermatologists after careful examination. The examination will include, of course, dermatologic physical therapy. It is probable that in time patients will for the most part consult only those dermatologists who have been certified by the board. It is to be hoped that when the time is propitious the members of the specialty of physical therapy will establish a certifying board for their own protection and for the protection of the lay public.

It is still difficult to obtain a comprehensive training in general physical therapy or even in dermatologic physical therapy, especially without visiting several or many medical centers. Every long term postgraduate course in practical dermatology should provide adequate training in dermatologic physical therapy. Such courses will do for the present, but much more is required for the future. In the premedical course it would seem advisable to devote more time to physics in terms of biologic reactions. The medical course might well include at least the fundamentals of physical therapy. The larger hospitals should have a physical therapy department in which the two-year rotating intern should spend several months. A physician who has received this elementary training is prepared to gain the most from postgraduate courses that include physical therapy.

It appears to be the general impression that physical therapy is synonymous with machine therapy—an entirely erroneous opinion. The most important agents in the general field of physical therapy are massage, rehabilitation, vocational therapy, posture, heat, solar radiation and the like. In dermatology it happens that x-rays are important, and they must be produced by electrical machinery. But even here, many natural physical agents are employed. In fact, it is doubtful if dermatologists have realized how heavily they have leaned on natural physical methods for therapeutic results. These agents include massage, posture, elastic stockings, strapping, exercise, rest in the reclining position, the action of moving air on exposed skin, water in the shape of wet dressings and baths, solar radiation, heat, cold, radium and so on.

There is a controversy as to whether the dermatologist should use physical therapy methods or should refer his patients to a physical therapist, roentgenologist, etc. There has been a similar controversy relative to other diagnostic and therapeutic methods—internal medicine, surgery, clinical laboratory work and so on. In private practice, the dermatologist can be as comprehensive and self-reliant as he desires within the scope of his ability. In institutional work it is more difficult to obtain this privilege. In many institutions the department of dermatology is hardly more than a clearing house. As I am an advocate of comprehensive dermatology, it is my contention that the department of dermatology in an institution should be, as far as is practicable, a self-sustained unit. But I do not advocate that this be accomplished by legislation. The director of the department and his staff must be able to use skilfully the many diagnostic and therapeutic methods necessary in dermatology and with them obtain better diagnostic and therapeutic results and do better research work and teaching than can be accomplished by complete institutional centralization or interdepartmental cooperation. When a larger number of dermatologists have demonstrated this comprehensive ability and have developed executive and organizing capacity, it is possible that there will be more self-sustained dermatologic units.

PHYSICAL THERAPEUTIC METHODS USED IN DERMATOLOGY

There are a number of physical methods used therapeutically in dermatologic practice. These consist of radiation, heat, cold, electricity, massage, posture, strapping, baths and wet dressings.

Radiation.—X-Rays: This agent has been of great practical service to the dermatologist. It is still the most efficacious single remedy in the armamentarium of the dermatologist. About eighty dermatoses are more or less amenable to its action. In some instances the roentgen rays constitute the only remedial agent that will cure or control a disease or give relief from distressing symptoms. In most cases the roentgen rays are used only as an adjuvant.

Injuries caused by x-rays and radium are still too common. Most of them are due to poor judgment rather than faulty technic, and they rarely follow irradiation by well trained dermatologists. With good judgment, diligence and modern technic, unfavorable results should be almost negligible.

There have been two valuable additions to roentgen therapy during recent years. One is the establishment of an international unit of quantity known as the roentgen. The other is the development of ionization dosimeters calibrated in roentgen units for use in routine practice. Unless used by those who understand the possibilities and limitations of these dosimeters, serious errors are likely to result, especially with unfiltered radiation, and they do not obviate the necessity for testing technic by the usual visible effects on human skin. In expert hands it is possible to record the dose in effective wavelengths (quality) and in roentgen units (quantity). As yet there is no universal standard for these dosimeters. Various instruments give different results with unfiltered radiation such as is used in the practice of dermatology. Nevertheless, they are extremely useful for the frequent checking of routine technic. My associates have been engaged for some time in a study of these dosimeters as applied to the technic used by American dermatologists. When the investigation is completed, the results will be published.

Grenz Rays: These are x-rays of a wavelength longer than those heretofore used for therapeutic purposes. They average about 2 angstrom units. These long wavelengths are absorbed largely by the epidermis, especially when thickened; therefore, the maximum effect is superficial. With doses ordinarily used in practice the reaction, while apparently severe, is superficial and usually disappears without subsequent sequelae. However, the beam of radiation is heterogeneous and contains some of the shorter wavelengths. With large doses, especially when repeated, sequelae such as atrophy and telangiectasia have been observed. Grenz rays are less hazardous than are x-rays of the usual wavelength, especially when applied to the deeper tissues. Therefore, they are especially useful for the treatment of diseases such as eczema, psoriasis and lichen planus when situated on the scrotum, scalp and eyelids, and also for the treatment of certain rebellious, circumscribed eruptions in infants and children. Satisfactory results have been obtained with this agent in a number of the dermatoses; but in my opinion, the efficacy of grenz rays is not nearly so great as that of ordinary x-rays. Because of the smallness of the area to which grenz rays can be applied, they are not suitable for the treatment of extensive eruptions.

Radium: In dermatologic practice, radium is used much less frequently than are the roentgen rays. In a given circumscribed cutaneous lesion, approximately the same result can be obtained by the proper application of either agent. There are, of course, exceptions. Beta rays are particularly useful for strawberry marks. Gamma rays have given better results in cavernous angiomas than have x-rays. Radium is more successful in malignant tumors. Radon can be used as implants and for lesions inaccessible to x-rays. But radium is not suitable for extensive lesions and eruptions, and most of the dermatoses seen in routine practice are of this type. The average dermatologist possesses a half-strength glazed radium applicator with which excellent results may be obtained in selected cases. He should, however, realize the limitations of such a small amount of radium and not attempt to cure epidermoid cancer and other equally malignant neoplasms with it, nor should he rent or purchase radon without adequate training in its use.

Ultraviolet Rays: It appears to be the general impression that ultraviolet irradiation is of great value in dermatology. This opinion is based largely on the clinical observations of those who are not dermatologists. Even in dermatology much of the knowledge of the effect of this agent on the various dermatoses is based on the clinical use of heterogeneous radiation without suitable controls. The possibility of spontaneous recovery, coincidence and the effect of air, temperature and visible light have not always been duly considered. There is evidence sufficient to justify the statement that ultraviolet radiation is of value in erysipelas and certain types of cutaneous tuberculosis. It is reasonably well established that ultraviolet rays are useful in adenoma sebaceum and for selected cases of acne vulgaris, pityriasis rosea, psoriasis, telangiectasia and indolent ulcers. There is a difference of opinion relative to the value of ultraviolet radiation in about thirty other dermatoses for which this agent is claimed by some to be therapeutically useful. While admitting occasional good results that appear to be due to ultraviolet radiation, the majority of dermatologists do not consider it to be an important agent in the management of these disorders.

In physics and biology it is an axiom that the effect of irradiation on human tissue is due to that portion of the radiation that is absorbed by the tissue. When employing ultraviolet rays and infra-red radiation, this fact should be kept in mind. While there is a difference of opinion regarding the penetrability of various rays, it is probable that the short wavelengths of the far ultraviolet are absorbed by 0.5 mm. or less of tissue. The longer wavelengths of the near ultraviolet are more penetrating, being absorbed by about 1 mm. of tissue. Visible solar radiation penetrates to a depth of about 5 mm. The short infra-red rays (near infra-red) penetrate to a depth of 20 or 30 mm., while the longer wavelengths of the far infra-red are absorbed by about 3 mm. or less of tissue. From the foregoing statements it is obvious that the far infra-red rays may produce severe burns without effecting the desired therapeutic effect. The maximum bactericidal action of ultraviolet radiation is in the comparatively nonpenetrating short wave range. One might mention many other characteristics, such as the production of erythema, pigmentation, effect on the cutaneous nerves, absorption by the blood, etc., which are characteristic of the various wavelengths. Suffice it to say here, however, that the dermatologist should consider all these features before purchasing ultraviolet and infra-red generators.

The erroneous impression prevails that ultraviolet radiation is harmless. As most dermatologists know, the injudicious use of this agent may cause undesirable systemic reactions; it may be the precipitating cause of lupus erythematosus and herpes simplex. It may change a quiescent inflammatory dermatosis into acute, active eruptions and even dermatitis exfoliativa. Pellagra, hydroa aestivale, sailor's skin, xeroderma pigmentosum and erythema solare perstans are etiologically related to the effect of light. In this connection may be mentioned erythema ab igne, caused by heat, and pernio and other conditions caused by cold.

Light of various colors, orange for instance, has been used in dermatology with results that were not encouraging.

Heat.—Heat therapy is quite widely employed in dermatology by means of conduction, convection, radiation and high-frequency electricity. Originally, heat therapy consisted of the application of heat by hot objects, such as a poultice and hot water. In recent years, radiant heaters have been popular as a source of infra-red radiation. At the moment, medical diathermy is the most popular method of applying heat therapy. In this form of heat therapy, the heat is generated in the tissue instead of being applied to the tissue.

In dermatology, heat therapy is of value for boils in the early stage of evolution. It is at times beneficial for the stasis and congestion accompanying certain chronic inflammatory dermatoses. It may be of some value in the treatment of onychomycosis. Applied as medical diathermy to the spinal region, it is thought by some to be of service in the management of lichen planus and scleroderma. Heat therapy in syphilis applied by means of hot baths, medical diathermy and radiant heaters has not been successful. The short radio waves are penetrating and cause an elevation of body temperature when properly applied. Experimental work is now being conducted with these wavelengths, with results that are at least encouraging.

The actual cautery is not used as much by dermatologists now as in former years, as it has been supplanted to a large extent by surgical diathermy. Heat obtained by focusing the sun's rays is used to some extent for destructive purposes; but the method is not popular.

Cold.—Freezing the skin with ethyl chloride or solid carbon dioxide is successful in some cases of larva migrans. The same method has been used for scabies and dermatophytosis with poor results. Cold compresses are used occasionally to provoke cutaneous reaction in the congested skin in certain chronic dermatoses. Ethyl chloride and solid carbon dioxide are used for the same purpose, especially when the eruption is circumscribed. Solid carbon dioxide is not now so popular as in former years, but it is useful for the destruction of warts, certain nevi and discoid lupus erythematosus. It is now possible to obtain hard blocks of solid carbon dioxide from the confectioner, who uses it for ice cream cartons.

Electricity.—With the exception of medical and surgical diathermy and electrolysis, electrotherapy is not used much in dermatology. Cataphoresis has thus far been of little value. The application of high-frequency sparks by means of a glass vacuum electrode for the production of hyperemia is used to some extent; but the method is of questionable value. The same statement may be made relative to the use of a negative galvanic current to soften scar tissue.

Electrolysis is a valuable therapeutic method, and should be more universally employed. It is useful for the removal of many small benign lesions, and it is the best available method for the permanent removal of superfluous hair. Dermatologists have neglected this aspect of physical therapy, with the result that many patients are compelled to go to cosmetologists and beauty specialists. Instruction in electrolysis should be included in the curriculum of postgraduate courses in clinical dermatology.

Massage, Posture, Etc.—It seems to be the consensus that massage is useful for scleroderma. It appears to be of some value in cases of hyperplastic scar tissue and perhaps for some of the chronic dermatoses. It is used for various types of alopecia.

Rest in the reclining position is necessary for some acute generalized eruptions. Elevation of congested extremities, the wearing of elastic stockings, prescribed exercise and rest and strapping are of value in cases of dermatitis hemostatica and indolent ulcers. Balneotherapy consisting of baths of various kinds, including the permanent bath for pemphigus, is used by nearly all dermatologists. In fact, if balneotherapy includes wet dressings and compresses and water as a vehicle for the application of heat, cold and various chemicals, it is indeed a widely used method.

Diathermy.—Medical diathermy signifies the application of a bipolar high-frequency current for medical purposes. The current is obtained from the primary winding of the high-frequency transformer. This used to be called the d'Arsonval or solenoid current. Its use in dermatology is limited.

Surgical diathermy is the application of a high-frequency current for the purpose of destroying tissue. In dermatology there are three types of high-frequency currents that are used for this purpose. The cutting current is obtained from the primary winding of the high-frequency transformer or inductance. This may be monopolar or bipolar, depending on the construction of the apparatus and the number of turns of the primary winding in the current. It may be damped or undamped. The voltage is low as compared with the other currents. The current cuts like a knife, and there is sufficient coagulation of tissue to seal the lymphatics and the small blood vessels. The electrode is usually a needle or a fine wire loop.

The coagulating current is obtained from the same source and it, too, may be monopolar or bipolar. The active electrode is usually a small needle. This current coagulates tissue to a distance of several or many millimeters in all directions from the needle electrode.

The desiccating current is monopolar and is obtained from the secondary of the high frequency transformer. This was formerly called the resonator or Oudin current, and its application was known as fulguration. The current has a comparatively high voltage and low milliamperage. This current dehydrates, desiccates or mummifies the tissue.

The various forms of surgical diathermy are employed for a variety of cutaneous conditions. With the desiccating current it is possible to dehydrate accurately a tiny lesion of the skin or to destroy a large superficial lesion. Electrodesiccation is used mostly for the destruction of certain nevi, warts, small areas of leukoplakia and many small, superficial benign lesions. Electrocoagulation is used mostly for the destruction of malignant neoplasms. The cutting current is employed to excise both benign and malignant new growths either alone or combined with electrocoagulation, radium and roentgen rays. It is also used with a loop electrode to remove the elevated portion of a large, thick keloid, after which roentgen rays are applied to prevent a recurrence. In selected cases of malignant neoplasms surgical diathermy appears to be superior to scalpel surgery because it seals the lymphatics and blood vessels and because it can be used in locations inaccessible to the scalpel.

Physical measures used for surgical purposes may be included under the general category of physical therapy, but they also belong to surgery. All surgical operations, whether performed with the scalpel or with some physical device, require for uniform success a knowledge of the principles of surgery.

RELATION BETWEEN GASTRIC AND RENAL DISEASES

CLINICAL OBSERVATIONS

JULIUS FRIEDENWALD, M.D.
AND
SAMUEL MORRISON, M.D.
BALTIMORE

Gastro-intestinal symptoms occurring during the course of renal disease are not uncommon. These may be so pronounced that unless an extremely careful investigation is made, erroneous conclusions may easily be drawn, the primary condition remaining entirely unrecognized. This is more especially observed in the incipient stages of certain chronic renal diseases as well as in persons in the later periods of life, complaining of indigestion with urinary symptoms of a comparatively unimportant type, in whom the blood chemistry and functional renal tests reveal the presence of definite renal lesions.

On the other hand, attention has frequently been called to the fact that digestive diseases in themselves may likewise primarily produce disturbances of renal function.

The intimate relation between the kidneys and digestive organs will, to a great extent, easily account for many of these manifestations. Owing to beginning decompensation in the circulatory system, an early enlargement of the liver as well as congestion of other abdominal organs is produced as the result of portal stasis, and in consequence a change in the gastric functions occurs, resulting in the production of digestive symptoms of a more or less severe type. A somewhat similar relation between the kidneys and digestive

Read before the Section on Gastro-Enterology and Proctology at the Eighty-Third Annual Session of the American Medical Association, New Orleans, May 13, 1932.

organs through the nerve supply is also recognized. Both are supplied by the vagus and sympathetic nerves, and any disturbance of the kidneys may be reflected through these paths to the gastro-intestinal tract, causing an interference with its functions. The upper portion of the digestive organs receives its sympathetic nerve supply from the splanchnic nerves, from which fibers are distributed to the celiac plexus and ganglion, aorticorenal ganglion and renal plexus and through the celiac ganglion to the superior mesenteric plexus and inferior mesenteric plexus. This intimate relationship may therefore also account for certain digestive symptoms so commonly arising as the result of renal disease. Likewise, as the result, on the one hand, of the absorption of toxic products due to disease of the kidneys or digestive tract there may follow, on the other hand, disturbances of the functions of the gastro-intestinal tract or of the kidneys.

In addition, the anatomic relationship between the kidneys and the abdominal viscera may have an important bearing in this connection. The relation of the anterior surface of the kidneys to the digestive organs varies somewhat on the right from that on the left side, the right being lower than the left, the left, however, being longer. The second portion of the duodenum is in direct contact with the hilus of the right kidney, while the hepatic flexure of the colon is in contact with the lower pole, and at times a part of the small bowel passes over the lower pole. The left kidney, in addition to being in close contact with the spleen, pancreas and suprarenal gland, is also closely related to the left side of the stomach. The descending colon not infrequently also passes over the lower pole of the left kidney, and the jejunum is in relation with its anterior surface.

The pathologic changes occurring in the mucous membrane of the stomach and intestine vary greatly with the character of the renal lesion. In the acute and subacute forms of nephritis with edema or those of the hemorrhagic type including the acute and subacute nephroses, the mucous membrane of the stomach is covered with mucus, while the glands of the stomach and intestines are swollen, irregular and filled with granular disintegrated cells and mucus. In the chronic forms of nephritis with edema, however, the mucous membrane assumes a grayish color and in some areas is intensely reddened. It is swollen, thickened and covered with an adherent tenacious mucus, which is cloudy and occasionally blood-stained. Ecchymotic patches and small hemorrhagic erosions may also be observed. The pyloric area is more markedly involved, though the inflammation may extend throughout the entire mucous membrane. The submucous and muscular coats are at times thickened. The glands of the stomach and intestine are enlarged, sacculated and dilated, the tubules being distorted in many areas, and no longer present their characteristic appearance. The glandular cells become cloudy, granular and infiltrated and finally undergo fatty degeneration. The principal and parietal cells cannot always be differentiated at this stage. Abundant small cell infiltration separates the glands, and extension of connective tissue may be noted passing from the mucosa between the glands. Mucoid transformation of the cells of the tubules is a prominent change, which may extend into the fundus of the glands.

In the chronic types without edema but with hypertension, known ordinarily as chronic interstitial nephritis, there is present usually an inflammatory increase in the interglandular connective tissue of the stomach and intestine, the mucous membrane undergoing a fibrous thickening, especially noted in the intima, resulting finally in the production of an atrophic gastritis. Not infrequently minute ecchymotic areas are observed in the mucosa of the stomach, or superficial ulcers or erosions in both the stomach and the intestine, which may gradually increase in extent. Sloughing ulcers have been observed in the large bowel associated with profuse diarrhea, often of serious form. After a considerable length of time, the inflammatory process may lead to a total destruction of glandular layers, the coats of the stomach undergoing thickening and atrophy and the mucous membrane and glands being replaced by round cells and connective tissue.

As a result of enlargement of the prostate, stricture of the ureter, kidney stone, movable kidney with or without the production of Dietl's crises, chronic infections, pyelitis or pyelonephritis, changes may take place in the stomach and intestine similar to those already described.

In the study of the interrelation of the disturbances of the digestive organs with those of the kidneys, the two following groups will be considered: (1) digestive symptoms occurring in renal disease, and (2) renal disease of gastro-intestinal origin.

DIGESTIVE SYMPTOMS OCCURRING IN RENAL DISEASE

Owing in part to reflex causes, but in a far greater degree to absorption of toxic products which are the result of renal disease, dyspeptic symptoms of more or less severe forms are often found to supervene. Whether this toxic substance is urea, as Elwyn[1] has recently again maintained, or a combination of this with other products is of minor importance in this connection. At first the toxin is accumulated to a slight degree in the blood and, being excreted in small amounts in the gastro-intestinal tract, gives rise to minor digestive upsets, but sooner or later, as the accumulation becomes more excessive, it is excreted to a far greater degree, giving rise to grave symptoms due to a consequent gastro-enteritis or ulceration.

When the toxic substance is excreted into the mouth through the salivary glands, it is decomposed with the formation of ammonia and produces the odor of urine in the breath. This causes a highly disagreeable taste in the mouth and a coated tongue. It is excreted through the gastric glands and then produces an irritation of the mucous membrane with symptoms of nausea, vomiting and anorexia. These symptoms of disturbed digestion in chronic forms of renal disease are often extremely pronounced and frequently overshadow those directly associated with the renal lesion. They necessarily vary according to the character and degree of involvement of the stomach and intestine. The symptoms characteristically observed are loss of appetite, nausea, vomiting, constipation or diarrhea, flatulence and pain following meals. Loss of appetite occurs as an extremely early symptom and may appear before the renal lesion is even suspected. It is sooner or later followed by vomiting after meals and not infrequently in the morning on a fasting stomach. In these instances nausea occurs on awakening and is followed by extreme retching and vomiting of mucus, which is alkaline in reaction, together with an admixture of bile and salivary secretion. Vomiting may follow immediately or occur several hours after meals; when appearing late, the vomitus contains undigested food remains with an admixture of mucus. In the milder types vomiting may be absent, though gastric distress, anorexia and a burning sensation in the abdomen are usually noted. Constipation, which is usually present at the onset, is sooner or later replaced by diarrhea with loss of flesh and anemia. Examination of the blood chemistry at this stage usually reveals a high nitrogen content and not infrequently an increase in creatinine. With improvement in the renal disease the digestive symptoms likewise show evidence of abatement.

---

[1] Elwyn: Am. J. M. Sc. 179: 149, 1930.

As a complication of nephritis, uremia may occur. The symptoms referable to the digestive tract are then largely due to toxic manifestations. The onset of uremia is accompanied by excessive nausea, vomiting, headaches and drowsiness. Food is badly tolerated and usually promptly rejected in an undigested form together with an admixture of mucus and bile. The breath becomes strongly ammoniacal. Obstinate constipation may alternate with excessive diarrhea. The diarrhea is frequently accompanied by pain, and the stools are occasionally blood stained. Urea has been observed in the vomitus, and when the kidneys do not carry off the toxic substances sufficiently, the excess will be eliminated through the gastro-intestinal tract. The stomach and intestine thus assist in this manner in the elimination of toxic products from the blood when these cannot be eliminated through the usual channels. The vomiting and diarrhea occurring in uremia are therefore, in a measure, compensatory mechanisms. Auguste[2] confirmed this observation in five patients affected with chronic nephritis with evidences of uremia and a high nitrogen retention in the blood, in whom a favorable outcome was brought about through duodenal lavage. Although death ensued within several weeks in all his patients, relief from all symptoms, that is, from uremia, headaches and loss of vision, was observed. Hugh Young[3] likewise called attention to the value of the duodenal tube as a means of combating the nausea and vomiting in uremic conditions.

In the acute forms of nephritis the onset may be of a fulminating character, associated with headaches, malaise, nausea .and vomiting, but these symptoms, including edema, usually develop gradually and finally become prominent.

In the chronic forms of nephritis with edema there is usually a secondary anemia, and the edema may include the gastro-intestinal tract, giving rise to fulness, distention, gas, discomfort following meals, nausea, persistent vomiting or constipation, diarrhea and loss of appetite. In this condition there are also present malaise, loss of strength and headaches, the blood pressure remaining normal or even low.

In the chronic forms of nephritis with hypertension or chronic interstitial nephritis, the onset is insidious, the symptoms occurring rather late. The early signs are largely those of fatigue and loss of strength and often weight, followed by headaches, dizziness, loss of appetite, fulness, distention, flatulence, dyspnea and finally symptoms of toxemia, manifested in the form of drowsiness and attacks of nausea and vomiting which become more and more frequent and persistent. Occasionally, abdominal pain, which may become severe and even suggest disease of the gallbladder, appears.

In renal disease associated with infection in the form of pyelitis or chronic pyelonephritis, digestive symptoms occur in the form of anorexia, nausea and vomiting, with pain and tenderness in the region of the kidneys and in the abdomen, not infrequently associated with chills and a rise in temperature. The pain may be localized in the loin, but frequently radiates to the right side of the abdomen.

The gastro-intestinal symptoms occurring as the result of renal ptosis may be insignificant or pronounced. This condition is usually associated with a visceroptosis, and many symptoms may be due to this disease. The most prominent are nausea, vomiting, abdominal pain, loss of weight, weakness, abdominal tenderness and a dragging sensation in the abdomen when the patient is in the erect posture. At times, intense colicky pains associated with Dietl's crises are manifested. In this condition, enlargement of the kidney is noted, and this organ, on palpation, is found to be extremely painful. As the urinary stasis becomes more pronounced, hydronephrosis, pyelitis or pyelonephritis may result, with chills, fever, nausea, vomiting and other digestive symptoms due to pressure.

The digestive symptoms occurring in nephrolithiasis and as the result of ureteral calculus or stricture are usually not pronounced or characteristic unless renal colic is produced. The symptoms ordinarily noted are nausea and vomiting, which may be periodic and persistent, epigastric pain and pressure, abdominal and lumbar pain, eructations, heartburn and constipation. The sudden onset of intense pain in the lumbar region, associated with weakness, nausea, vomiting and signs of shock, together with the urinary findings, points clearly to the presence of renal colic. However, when the symptoms relating to the urinary tract are atypical, the digestive symptoms may become so pronounced as to give rise to the picture of a primary dyspeptic disturbance. At times the constipation associated with this condition may become intense and be accompanied with such extreme abdominal distention as to give rise to the erroneous diagnosis of intestinal obstruction or an acute peritonitis. Cystoscopic and roentgen examinations will ordinarily aid in establishing the correct diagnosis.

In other instances the gastro-intestinal symptoms may be of a less severe but more chronic type, consisting of nausea, abdominal discomfort, pain, eructations and occasional vomiting, while the urinary manifestations may again be so mild in character as to be entirely overlooked. A thorough examination including a urinary investigation will usually point to the correct diagnosis.

Occasionally a stone in the pelvis of the kidney will produce symptoms resembling duodenal ulcer or cholelithiasis, giving rise to pain several hours after meals with signs of hyperacidity or reflex colicky pain in the upper part of the abdomen. Here, too, a thorough investigation will aid in establishing the diagnosis.

In those instances associated with prostatic obstruction, the digestion not infrequently becomes markedly impaired, and nausea, vomiting, eructation, abdominal pain and emaciation become so prominent that the presence of carcinoma of the stomach may be suspected. There are often present marked abdominal distention, oppression, dyspnea, flatulence and diarrhea with intense thirst. The tongue, under these considerations, becomes reddened, dry and furred, and the mucous membrane of the mouth presents a glazed appearance.

The Gastric Secretion in Renal Disease.—Authorities are by no means in accord regarding the changes occurring in the gastric secretion in chronic nephritis.

Van Valzah and Nisbet[4] considered hyperacidity common in the early period of the disease with the development of a low acidity as the disease progresses. Biernaki[5] and Jones[6] pointed out that the gastric secretion is greatly diminished, while Zipkin[7] and Krakow[8] found hyperacidity more frequent.

According to our observations, in the early stages of chronic renal disease before the occurrence of edema or uremia slight changes are noted in the gastric secretion; however, hyperacidity is occasionally observed. At a later period following the onset of renal insufficiency there is a reduction in the gastric secretion due largely to a resulting secondary chronic gastritis. During the acute exacerbations of chronic nephritis, hypoacidity or anacidity not uncommonly occur and this is frequently replaced by a normal acidity or even hyperacidity during the period when renal sufficiency is again restored. Free hydrochloric acid is also known to diminish during uremic attacks.

RENAL DISEASE OF GASTRO-INTESTINAL ORIGIN

Occasionally as the result of pyloric or high intestinal obstruction renal disease is known to occur. In this condition tetany may appear and the signs of severe toxemia may be manifested. Brown, Eusterman, Hartman and Rowntree[9] have especially called attention to the renal disturbances noted in many of these cases. The evidence of the toxic injury to the kidneys is demonstrated, according to these observers, by the albuminuria and cylindruria, the functional impairment of the kidneys with increased nonprotein nitrogen, creatinine and urea in the blood and a definite diminution of the phenolsulphonphthalein output. In addition, the clinical and pathologic picture points definitely to a nephritis. As a result of the pyloric or upper intestinal obstruction a toxemia is produced, often leading to an alkalosis of a more or less severe type. Brown and his co-workers described eleven cases of this character exhibiting duodenal intoxication with renal disturbance. The gastric symptoms were mainly nausea and vomiting. Headaches were common. In the chronically obstructed group intermittent crises occurred at intervals of a few days with vomiting of excessive quantities of serous fluids. With the emptying of the stomach great relief was obtained for a time. Not uncommonly in the more pronounced forms, tetany or tetany-like symptoms develop. Due to violent vomiting and the resultant depletion of fluid, symptoms of shock are produced with a fall in blood pressure, weakness, an apparent increase in hemoglobin and finally delirium and cerebral excitement. The urinary secretion is diminished and albumin, casts and even red blood cells are observed. With the development of the toxemia, the blood chemistry reveals, as has already been noted, marked changes. There is a decrease in the blood chlorides and an increase in the carbon dioxide-combining power of the blood, with an increase in the nonprotein nitrogen, urea and creatinine. The phenolsulphonphthalein test reveals a marked disturbance of renal function. The renal lesion, according to these observers, presents the clinical picture of a degenerative type often noted in experimental nephritis. An interesting fact, however, is that edema, an increase in blood pressure and retinal hemorrhages do not occur. In six cases studied at autopsy, according to Brown and his co-workers, marked evidences of toxic nephritis were presented. The tubular epithelium showed degenerative changes, and granular and fatty changes were also commonly observed. Marked dilatation of the stomach and duodenum was also noted at autopsy. Pfeiffer[10] has more recently called attention to the alkalosis due to pyloric stenosis associated with the characteristic changes in the blood chemistry as well as urinary symptoms similar to those observed in acute glomerulonephritis.

Tileston and Comfort[11] also observed the great increase in the nonprotein nitrogen and urea of the blood in acute intestinal obstruction, and considered this due to increased destruction of tissue. They noted that the retention of nitrogen disappears following operation for relief of the obstruction and that the retention is associated with indicanuria.

Cooke, Rodenbaugh and Whipple[12] observed an increase in nonprotein nitrogen in the blood but without renal lesions in their first experiments on animals in high intestinal obstruction. In a subsequent series of experiments, however, McQuarrie and Whipple[13] proved conclusively that renal function was greatly impaired in this condition.

Hardt and Rivers[14] called attention to a group of patients undergoing alkaline medication for peptic ulcer in whom toxic symptoms were produced. These patients presented an albuminuria, cylindruria and a rise in blood urea and alkali reserve. There was no evidence, however, of renal disturbance except in two instances in which an acute exacerbation of a chronic nephritis was observed at autopsy.

The cases reported by Tucker[15] are of especial interest. In eight instances, in which uremia developed following gastro-enterostomy, this condition appeared to be the immediate cause of death. In four of these cases an acute process was revealed, developing on a previously existing chronic nephritis.

Zeman, Friedman and Mann[16] studied four cases of pyloric obstruction with special reference to the microscopic changes produced in the kidneys. Of the four, two presented clinically the symptoms of tetany of gastric origin. The renal changes at autopsy in all four revealed identical conditions. There were degenerative changes noted in the cells lining the spiral and straight portions of the first convoluted tubules. In many sections these cells were found to be necrotic and infiltrated with granules staining blue with hematoxylin, which was interpreted as due to calcium salts. Similar changes are frequently observed in mercuric poisoning. The kidney changes are of a degenerative type and are best described, according to these observers, as a toxic degenerative nephrosis. They also called attention to the fact that gastric tetany was first described by Nazzari in 1904, and suggested that the primary factor is a pyloric or high duodenal obstruction with persistent vomiting and as a result tetany and renal changes are produced. Zeman and his co-workers found that in thirteen cats in which the pylorus was tied off, it was possible to produce lesions in all respects similar to those described in human beings. The early changes consisted in necrosis of the kidney cells as described, with calcification within forty-eight hours following operation. Grossly, the kidneys showed cloudy swelling and congestion, especially in the pyramids. Microscopically there was a diffuse tubular degeneration with necrosis and calcification occurring in the spiral and terminal parts of the convoluted tubules and later in the tubules adjacent to the glomeruli. The clinical data in the animals revealed a rise in the carbon dioxide-combining power of the plasma with lowered blood plasma chlorides and an increase in the nonprotein nitrogen of the blood.

The pathologic renal changes are in accord with the clinical observations and laboratory data. The rôle of the kidney is important in this connection since the renal lesion appears as an outstanding pathologic change in pyloric and high intestinal obstruction.

Crohn[17] described a case of prolonged and severe atony of the stomach in which gastric retention continued notwithstanding a gastro-enterostomy. Death occurred with symptoms of decreased urinary function, showing albumin and casts in the urine, and with stupor and convulsive seizures in the extremities. These symptoms could be interpreted at autopsy only in the light of a degenerative toxic nephritis.

Bennett[18] also drew attention to the close association between gastric and renal disease, and presented the following table in evidence:

Progressive Renal Disease	Nonmalignant Pyloric Obstruction
1. Acid accumulation in the blood	Acid loss from vomiting
2. Acidosis	Alkalosis
3. Phosphorus retention	Chloride loss
4. Nitrogen retention	Nitrogen retention
5. Calcium reduction	Calcium reduction
6. Twitching and convulsions	Tetany

He concluded that not only may renal disturbances produce marked alteration in the blood chemistry, but the chemical changes in the blood due to high duodenal and pyloric obstruction may occasion extensive renal lesions.

While severe types of toxemia may follow partial or complete pyloric or duodenal obstruction, resulting finally in renal damage of more or less severity, a similar condition due to intestinal stasis may likewise occur, though perhaps to a far lesser degree. This is especially noted in persons in the later years of life who have been subjects of persistent gastro-intestinal toxemia extending over a period of many years and in whom the gradual but definite onset of this condition is observed. Toxemias of these types are due at times to intestinal stasis. They have been noted in duodenal stasis in which gastric retention and profuse bilious vomiting occur. The profound toxemia in these instances may even be associated with marked dehydration, shock and occasionally attacks of tetany. In this state there are present an increase in the nonprotein nitrogen and urea of the blood, a reduction in the chlorides and a rise in the carbon dioxide combining power of the blood plasma with an alkalosis.

Landau, Jochweds and Pekielis[19] have reported a case of this type due to carcinoma in which this complication occurred and in which the changes just referred to were observed. But a similar condition may likewise arise, though to a lesser degree, in intestinal stasis, whether ileac or colonic. In such instances, associated with long-continued habitual constipation of an aggravated type and the usual symptoms of fatigue, depression, headache, anemia, anorexia, nausea and so-called bilious attacks, one frequently finds a large excess of indican in the urine. Traces of albumin and the presence of hyaline casts are noted and finally in increasing amounts with granular casts and indican. In certain of these cases a rise in the nonprotein nitrogen and urea in the blood is gradually manifested and the renal function becomes impaired. At this period, hypertension often associated with cardiovascular disease becomes definitely established.

In this connection it is interesting to note that Redewill, Potter and Garrison[20] have recently called attention to the close relationship existing between the gastro-intestinal and genito-urinary tract and the importance of the colon as the site of focal infections in the causation of such diseases as chronic pyelitis, cystitis and prostatitis.

While absolute proof is still lacking that renal disease is definitely due to the toxic products eliminated through the digestive tract, the constant presence of large amounts of indican in the urine and the gradual onset of the renal disease following many years of digestive disturbances are at least suggestive in some instances of this relationship. As a further evidence in this direction is the fact that following the disappearance of the intestinal stasis under appropriate treatment, the urinary disturbance will not uncommonly be overcome.

Finally, it is interesting to note that certain gastric diseases modify the urinary composition. In gastric retention due to pyloric stenosis the quantity of urine excreted is markedly diminished and albuminuria may likewise occur. It is questionable, however, whether any marked damage is inflicted on the kidneys following the milder, though even prolonged, forms of gastro-intestinal disturbance.

SUMMARY

Attention is directed to the intimate relationship between disturbances of the kidneys and those of the gastro-intestinal tract. This is accounted for partly by the anatomic relations between these systems and their nerve and blood supply, as well as in a large degree by developing toxemias. The various lesions occurring in the digestive tract as the result of renal disease are considered. Early symptoms noted in connection with the digestive tract in renal disease are not uncommon. These are extremely pronounced at times and frequently overshadow those directly associated with the renal lesion. These symptoms should be constantly held in mind, inasmuch as relief can often be obtained under these conditions only by direct treatment of the primary disease. The gastro-intestinal symptoms occurring in uremia are toxic in nature; there appears to be an attempt in the diarrhea and vomiting to eliminate the toxin, which may be considered in a way as a compensatory measure.

On the other hand, as the result of pyloric or high intestinal obstruction, renal disease may be produced associated with profound toxemia. It is also quite possible that prolonged duodenal, ileac and colonic stasis may likewise give rise to pronounced forms of toxemia, finally leading to renal involvement. The colon may also act as a focus of infection in the production of certain urinary lesions.

In the study of renal and digestive disease it is therefore of importance to bear in mind the reciprocal relation of these organs to one another in order to arrive at correct conclusions in diagnosis and consequently in treatment.

ABSTRACT OF DISCUSSION

Dr. Sidney K. Simon, New Orleans: The authors have demonstrated a point that gastro-enterologists are prone to lay little stress on and that is the point of all inclusiveness of diseases of the intestinal tract, and the causes and the relationships they bear through reflex and toxic sources to other organs of the body. The stomach in a way may be considered as the alarm clock of the entire body, sounding an alarm when pathologic distress exists in neighboring and in many instances in far-removed structures. Such instances are matters of common knowledge, but the point has not been sufficiently stressed in reference to the genito-urinary system. This is notably true in uremia and the frequently participating digestive disturbances that many times arise before the renal phenomena appear.

Dr. Seale Harris, Birmingham, Ala.: The general practitioner first sees the patient with early manifestations of failing kidney function; and in such cases if he recognizes that the anorexia, vague abdominal discomfort, nausea, vomiting and diarrhea, and sometimes obstinate constipation, are due to metabolic changes of renal origin, he can institute treatment that may prevent irreparable damage to the kidneys and myocardium. If he fails to make the correct diagnosis and treats the symptoms as of primary gastro-intestinal origin, allowing his patient to become dehydrated and toxic from retained urinary products, his trusting patron may be doomed to an early death from uremia or a damaged myocardium. In any case of nausea and vomiting, with either constipation or diarrhea, in a man or woman past 50, in which such symptoms cannot be accounted for otherwise, it is safest to consider that they are due to renal dysfunction and treat the patient accordingly. The prompt administration of sufficient fluids and soluble carbohydrates in such cases saves lives. If the patient cannot retain water and soluble carbohydrates such as coffee or tea, orange juice, lemonade, orangeade, dextrose (corn sugar) or glucose (corn syrup) solutions, at least three or four quarts of fluids a day, dextrose solutions may be given by hypodermoclysis (5 per cent solution) or intravenously (10 per cent solution). If there is constipation, plain water may be given by proctoclysis after a cleansing enema. It is futile and even harmful to give glucose or other carbohydrates by rectum. In cases of suspected renal damage, salt solutions should be given sparingly, not more than 1,000 cc. a day. While sufficient fluids should be given, it is unsafe to give more than 4,000 cc. a day, because of the danger of what Rowntree calls "water intoxication," or of overworking damaged kidneys, or of overwhelming a toxic and failing myocardium. Of course, it is desirable to make renal function tests (phenolsulphonphthalein), and chemical studies of the blood (nonprotein nitrogen, urea, creatinine, carbon dioxide combining power of blood plasma, and so on) in such cases to determine the functional capacity of the kidneys and the character and degree of the toxemia (uremia, azotemia, acidosis or alkalosis); but the general practitioner, who may not have laboratory facilities available, should play safe by treating the patient with gastro-intestinal symptoms of suspected renal origin as if he were positive of the diagnosis of primary kidney disease. In men past 50 whose first symptoms are anorexia, nausea, vomiting and diarrhea or constipation, with or without fever, unless known to be due to food infection or other demonstrable causes, an examination of the prostate or a catheterization for residual urine may clear up the diagnosis.

Dr. A. L. Levin, New Orleans: Postoperative biliary vomiting is of frequent occurrence and is often a serious complication. This problem has been studied carefully by Dr. Eusterman, in collaboration with Drs. Brown, Hartman and Rowntree. Their studies of the subject have been described in the 1923 volume of the Collected Papers of the Mayo Clinic. The conclusion was that toxic nephritis soon develops if the postoperative biliary regurgitation is not corrected early. One must bear in mind that postoperative biliary regurgitation occurs not only in laparotomy cases but also in cases in which the abdomen is not opened. Fetor oris is another unexplained phenomenon. Dr. Alvarez explains it on the basis of reverse peristalsis. It has been demonstrated that urea is quite often eliminated by the stomach; in cases of kidney insufficiency, it is probable that an excessive amount of eliminated urea will produce fetor oris. The authors stress the close relationship between the internist and the gastro-enterologist. I would suggest the inclusion of the surgeon in this partnership.

Dr. Julius Friedenwald, Baltimore: In a study of digestive diseases one is too likely to forget that there is an interrelationship between digestive disturbances and other organs, and it was our object in this paper to direct attention to the reciprocal relationship that exists between various systems and in this instance between the digestive and renal systems.

THROMBO-ANGIITIS OBLITERANS

RESULTS OF SYMPATHECTOMY

ALFRED W. ADSON, M.D.
AND
GEORGE E. BROWN, M.D.
ROCHESTER, MINN.

Thrombo-angiitis obliterans is a peripheral vascular disease, characterized by thrombosis of the peripheral arteries and veins, resulting in intermittent claudication, localized pain, edema, ulceration and gangrene of digits, and in the later stages of the disease,[1] in massive gangrene. Besides the process of thrombosis, vasomotor spasm of principal unoccluded and collateral arteries is found which aggravates the symptoms produced by the occlusion of arteries and veins, and which, if relieved, ameliorates the symptoms, preserves digits and extremities and aids materially in rehabilitating the patient. Patients with mild symptoms may not require special treatment, whereas those with moderately advanced symptoms may respond to medical care. However, since these attacks are prone to recur in the affected extremity with extension to the opposite extremity, methods of treatment with more permanent effects have been sought. Our experiences with sympathetic ganglionectomy and trunk resection in the treatment of Raynaud's disease due to vasomotor spasm of peripheral arteries led us to employ the same surgical procedure in thrombo-angiitis obliterans, when vasomotor spasm was a contributing factor in the production of symptoms, and we herewith submit a study of 100 cases in which bilateral operations have been performed at the Mayo Clinic from 1925 to 1932.

ETIOLOGY

The specific etiology is still undetermined. Some investigators hold that the disease is due to specific infection or to toxic agents. It is most common among young men (98 per cent) who are engaged in active

exercise, but it also occurs among men occupying sedentary positions, and occasionally it has occurred among young women. It is supposed to be more prevalent in the Hebrew race, but it has been found to develop in all races. Some investigators believe that the use of tobacco, especially if in excess, is a causative factor. The exposure to cold has a deleterious effect on the patients.

PATHOLOGY

The gross characteristics of the vessels affected by thrombo-angiitis obliterans depend on the stage of the process in which they are examined. If an affected vessel is opened in the longitudinal direction, there may be some noticeable thickening of the wall, even in the absence of occlusion of the lumen. If the process is advanced, there is extensive induration of the adventitia and the surrounding zone. The artery, vein and nerve become densely adherent, and this may be so extreme that they are separated with difficulty. The arteries are more frequently obliterated than their accompanying veins. The occlusion extends for variable lengths and then stops. Sometimes occlusion occurs at two different levels in the vessel, and the lumen between may be patent. On [2] opening an occluded vessel in the longitudinal direction, starting above the point of firm occlusion, one first notices, if the disease is progressing, a soft red adherent thrombus. In a short distance this may be replaced by more firm yellowish-brown material, and the lumen here is obviously much smaller and much more difficult to follow. This may run for a considerable distance along the course of the vessel, and then may be replaced again by a red thrombus, which is possibly a propagation of the clot. If the lesion is still further advanced there will be dense yellowish-white material completely occluding the lumen, so that it is impossible to open the vessel through the lumen in the longitudinal direction. If pressure is made on the vessel here, a minute drop of blood may be expressed from a tiny canal in the occluding substance. The vessels are not brittle as in advanced arteriosclerosis; nor in the patent lumens are there markedly irregular encroachments as are occasioned by an atheromatous process. The vessels, however, are indurated. The nerves are often closely bound to the vessels by tissue which has the characteristics of scar tissue.

The microscopic appearance in this disease naturally depends on the stage to which the disease has progressed in any one particular area. One of the earliest microscopic changes in the walls of the vessels is the presence of lymphocytes. Coincident with the appearance of the lymphocytes are changes within the wall of the vessel. The nuclei of the endothelial cells become larger, and the cells become more numerous. Connective tissue cells also exhibit proliferative activity. The older lesions show a marked increase in the density of the connective tissue of the adventitia as well as thickening of the intima. In the older lesions the fibrosis becomes extreme between arteries, veins and nerves. The striking changes in the media are exudative and proliferative, with preservation of the muscular layer. The changes within the intima are distinctly proliferative, both in arteries and in veins. The intimal thickening is cellular, especially on the free border, and these cells have large oval nuclei, which tend to range themselves in a radial distribution with the long axis of the vessel. The proliferative process in the intima, though marked, rarely continues until occlusion has taken place. Hence, it has been assumed that the thrombosis that actually takes place has been initiated by the same factors that have been responsible for the proliferative changes in the walls of vessels. The thrombus goes through all of the changes from a red blood clot to an organized fibrous band. In the later stages canalization and partial recovery of the arterial circulation may occasionally result.

SYMPTOMS

Intermittent claudication is one of the earliest symptoms and undoubtedly is due to anoxemia brought on by exercise. This is followed by or associated with postural color changes, that is, rubor with dependency and pallor with elevation. If the disease progresses, localized continuous pain may be present during the period of rest. Trophic changes are manifested by nonhealing abrasions from trauma, ulcerations of digits and the development of localized or massive gangrene. The disease usually progresses slowly and may remain temporarily quiescent in any one of the earlier stages. In some cases the disease never progresses to ulceration and gangrene, whereas in others the symptoms respond favorably to medical treatment, but more often it slowly involves the opposite extremity. In reviewing a series of 240 cases of thrombo-angiitis obliterans, Barker [3] found that the disease involved the lower extremities in 60 per cent; it affected the upper extremities alone in 2 per cent, and both upper and lower extremities in 38 per cent. It further was observed that the disease would sooner or later become bilateral even though more prominent in one extremity. In reviewing these statistics of cases it was learned that the disease progressed until it became bilateral in 98 per cent of the cases.

MEDICAL TREATMENT

Medical treatment consists of changing occupation in order to avoid continuous standing on the feet during work, and avoidance of trauma and exposure to cold. When hospitalization becomes necessary, rest in bed for several weeks is essential, and the cautious employment of local dry heat, contrast baths, hot mild antiseptic baths for extremities and bland antiseptic dressings are valuable measures. The administration of protein for the purpose of producing fever and vasodilatation in collateral and nonoccluded arteries is the most effective method of relieving symptoms and encouraging the healing of abrasions and ulcers. Vaccine therapy may be continued in conjunction with the previous medical measures following dismissal from hospital. The doses of vaccine necessarily will vary with individuals, but usually range from 25,000,000 to 75,000,000 of Lederle's triple typhoid vaccine; Lilly's antigen H vaccine is equally effective. Numerous other methods such as the administration of hypertonic saline solution, sulphur and oil, and acetylcholin by injection have been tried, the results of which cannot compare with the vaccines mentioned.

Records show that 56 per cent of patients were markedly improved following active treatment and that the incidence of amputation of leg or hand, which was 25 per cent, in cases in which treatment was inadequate or was not given, had been reduced to 14 per cent. Although medical treatment has been effective and the incidence of amputation has been lowered, progression of disease developed in many cases, which stimulated us to look for more effective methods of treatment. This led to the employment of sympathetic ganglionectomy and trunk resection for a group of patients suffering with this disease. Since we had no criterion to follow in the selection of suitable cases at the beginning of the investigation, we were compelled to progress by trial and error, but as experience developed we have found that we can determine preoperatively the patients who will respond to sympathectomy. Study of the cutaneous temperature revealed that we can reproduce by sympathectomy increased blood flow and the increased skin temperature produced by vaccine therapy and that these effects remain continuously increased, whereas the effects of vaccine therapy are only temporary.

VASCULAR STUDIES

In[4] a search for some means to determine the flow of blood to an extremity, the capillaries were examined, and elimination of heat[5] and surface temperature were measured. These procedures do not estimate exactly the volume flow of blood, but give relative estimates; one can observe the number of capillary loops to a given field and can determine the rate of flow of the corpuscles and the elimination of heat and the temperature of the skin that are dependent on the flow of blood. By the Stewart-Kegerreis calorimeter the radiation of heat before and after operation could be determined, but it was not until Brown suggested recording the temperature of the skin before fever had been induced, and during its course, that there was any accurate knowledge concerning vasospasm. The thermocouples of the electrothermometer are fastened to the various portions of the fingers, toes, hands, feet and body, in preparation for readings of surface temperature. First, readings are recorded of the temperature of the room, and of the mouth and surface of the skin. Thus, corrections can be made for the environmental temperature, and the temperature of the mouth and skin can be compared with the corresponding temperatures of a normal person, and with the readings taken during the height of fever. The fever is produced by administering, intravenously, a foreign protein, for example, 5,000,000 to 75,000,000 triple typhoid vaccine. The dose depends on the weight and sex of the patient. Hourly readings are made until the maximal rise of fever has been obtained. These readings are compared with the initial temperatures, to determine the ratios of increased temperature. General, regional and spinal anesthesia produce vasodilator effects and can be employed instead of administration of protein.

In studying the temperature of a normal person, it will be observed that the temperature of the mouth may have increased as much as an average of 2 C., whereas the temperature of the skin over the digits will have increased 4 to 6 C., or two to three times the mouth temperature, indicating that the peripheral arteries have been opened by inhibition of the vasomotor center and that more blood has been permitted to flow to the periphery. In cases of vasospastic disorder, the difference in temperatures is still greater, since the initial surface temperature of the digits is lower than that of a normal subject exposed to the same room temperature. In cases of general arterial sclerosis there may be little, if any, difference in the skin temperatures before and after administration of the foreign protein, indicating that the vessels are incapable of relaxing to allow increase of the flow of blood to the periphery. In cases of thrombo-angiitis obliterans it is possible to determine whether there exists an element of vasomotor spasm of the collateral vessels and unoccluded arteries; it is possible, too, to determine by individual readings the condition of each digit. Therefore, the test serves as an index, and unless the rise in temperature of the skin of the digits is two or more times greater than the rise of the oral temperature, the condition is considered inoperable. The test also permits determination of the degree of collateral circulation in different portions of the same digit. This aids in arriving at a prognosis concerning the preservation or loss of digits with ulcerated tips.

Further, to substantiate the opinion that vasomotor spasm exists and is due to stimuli of central origin carried over postganglionic gray rami to the arteries, instead of being due to a local fault[6] in the arterial walls, we have observed that increased blood flow with resulting increased temperature is readily produced by anesthesia of the vasomotor nerve by nerve block and regional and spinal anesthesia. In cases of Raynaud's disease the color changes are immediately abolished by anesthesia, and during the anesthesia they cannot be reproduced by emotional stimuli or exposure to cold. Similar results are obtained by a thorough interruption of gray rami, which is most effectively accomplished by removing the sympathetic ganglions with resection of trunks carrying vasomotor fibers. Following cervicothoracic ganglionectomy the retinal arteries and veins have been found to be dilated from one and a third to one and a half the preoperative size. Repeated calorimetric and cutaneous temperatures in cases of sympathectomy have revealed that the increased blood flow has been maintained for seven years in the cases in which operation was first performed.

SELECTION OF CASES

The real problem is to select suitable cases for operation and to decide when operation is indicated.[7] It is obvious that vasodilatation cannot be produced in an arteriosclerotic or occluded artery, and that surgical intervention is useless unless there is positive evidence of vasospasm in the remaining nonoccluded arteries. The operation is not indicated in the milder cases or in those in which response is quick and favorable to medical treatment. In advanced cases of massive gangrene the condition is likewise nonsurgical unless it is hoped to effect a lower amputation than otherwise would be required. Following amputation, sympathectomy may be indicated to preserve the opposite extremity.

The operation has proved to be of greatest value in slowly progressive cases and in those in which patients cannot afford or are unable to sacrifice the time required to rest in bed and receive local heat, contrast baths and vaccine therapy. During examination such patients are classified according to an outline proposed by Brown, Allen and Mahorner.[2]

Slow Progression.—This is the most common type. Coldness of the feet is usually the first symptom, followed by excessive fatigue of single digits, the arch of the foot, the wrist, ankle, calf or forearm. Excessive fatigue gradually changes into and is replaced by the pain of claudication occurring in similar areas which progresses and produces an increasing degree of disability. Color changes with change of posture are followed by trophic changes which occur spontaneously or are incited by incision of toes, removal of toe-nails, accidental trauma, amputation of toes or the application of blistering ointments. With the occurrence of trophic changes, the pain is sharply accentuated and becomes almost unbearable. The gangrenous areas increase in extent, necessitating amputation, or healing may occur in a group in which pain can be relieved. The extremities are cold; there is excessive pallor with elevation and abnormal rubor with dependency. Pulsation in the arteries is diminished or absent. The entire process is completed in from four to eight years.

TABLE 1.—*Incidence of Operation Among Men and Women, Average Age, Average Duration of Symptoms on Admission, and History of Amputation Previous to Admission*

Thrombo Angiitis Obliterans Treated by Sympathectomy	Operations on Men	Operations on Women	Average, Age, Years	Average Duration of Symptoms, Months	Previous Amputations
Group 1, uncomplicated					
Disease in upper extremities	3	1	39	75	Legs, 2 Arm, 1
Disease in lower extremities	17	2	35	41	Legs, 3
Group 2, with ulcers					
Disease in upper extremities	1		34	30	
Disease in lower extremities	42	1	40	59	Legs, 4 Toes, 7
Group 3, with gangrene					
Disease in upper extremities	10		36	35	Legs, 2 Fingers, 2
Disease in lower extremities	26	1	39	57	Legs, 2 Toes, 2
Total	99	5	35.5	49	

Absence of Progression.—In this type mild symptoms of vascular insufficiency (excessive fatigue or the pain of claudication) progress slowly for a time and then remain stationary. The extremities are cold, the arteries are obliterated, and postural color changes are present. Trophic changes other than proliferation of the nails and increased thickening of the skin over the weight-bearing area do not occur. Disability is minimal in spite of symptoms which may have endured from eight to twelve years.

Circulatory Compensation.—This type is not widely recognized, although it is fairly common. Shallow ulcers do not progress and after from six months to a year healing occurs. Gradually other symptoms largely disappear, leaving the patient with extremities approximately 80 per cent adequate for all needs. With care patients in this group may go on indefinitely with extremities functioning sufficiently well for all ordinary needs. Weber[8] has noted the return of pulsation in an obliterated radial artery, and this has been observed in several of our cases.

Acute Fulmination.—In this type the clinical syndrome is the antithesis of slow progression. Claudication appears relatively suddenly and progresses rapidly. The rest pain is severe before gangrenous changes occur and greatly accentuated afterward. Edema and lymphangeitis are present around the gangrenous area and there may be slight fever and leukocytosis. The gangrene progresses rapidly; the pain is unbearable and intractable to all measures. Amputation is necessary. The process may be complete after from three months to one year. This clinical syndrome may occur at any time in the clinical course of cases presenting a previous course outlined in the first and second groups.

On completion of the examination, which includes laboratory and vascular studies, we decide on the course of treatment, basing our judgment not only on the condition of the vascular system but on the present status and course of the disease. As previously stated, the operation is not employed in mild cases without ulcer; neither is it employed in cases in which there has been no progression nor in which the circulation has become compensated. It is never wise to urge operation during the acute stage of inflammation with active cellulitis. This type of patient should be hospitalized and treated medically from three to six weeks.

The slowly progressive cases, which include most cases of thrombo-angiitis obliterans, are most suitable for sympathectomy, and even then when extensive ulcers or gangrenous digits are present, we are inclined to hospitalize patients for two or three weeks under vaccine therapy in order to determine how the individual patient is going to respond to the vasodilating effect obtained by administration of protein before sympathectomy is performed. If the disease affects both the lower and upper extremities, we usually carry out a sympathetic ganglionectomy and trunk resection to interrupt the vasomotor fibers to the extremities affected first, and then wait six weeks until the patient has thoroughly recovered before performing the second operation. We usually perform bilateral sympathectomy even though the disease appears to produce symptoms in only one extremity, since ultimately it is almost sure to involve the opposite extremity, and since sympathectomy has apparently controlled the process and preserved the opposite extremity. However, recurring phlebitis may develop in either extremity following sympathectomy but this, aside from producing localized pain and edema, does not jeopardize the life of the extremity.

TABLE 2.—*The Incidence and Relief of Intermittent Claudication and Rest Pain*

Thrombo Angiitis Obliterans Treated by Sympathectomy	Operations	With Intermittent Claudication	Relieved of Intermittent Claudication	With Rest Pain	Relieved of Rest Pain	Continuance or Recurrence of Pain
Group 1, uncomplicated						
Disease in upper extremities	4	0		3	2	1
Disease in lower extremities	19	17	16	8	5	1
Group 2, with ulcers						
Disease in upper extremities	1	0		1	1	0
Disease in lower extremities	43	36	33	36	34	7

Disease in upper extremities	10	0		10	10	0
Disease in lower extremities	27	20	12	25	17	8
Total.....	104	63	61	83	69	25

The average degree of improvement in intermittent claudication and rest pain was 85 per cent.

SURGICAL TECHNIC

As the surgical technic has been described previously,[9] we shall not go into details, as it is generally accepted that the vasomotor innervation of the arteries

and veins does not run centrifugally along the vessels but that the vessels receive their innervation at various levels corresponding to the musculocutaneous segments. Although Leriche conceived the idea that vasodilation might be accomplished by interrupting the vasomotor fibers by a periarterial stripping operation, the operation was not of sufficient scope to include all of the nerves. If the vasomotor fibers are divided by ramisection or ganglionectomy and trunk resection, it is immaterial which method is used so long as they are completely resected. In treating thrombo-angiitis obliterans of the toes and feet we prefer to use the abdominal transperitoneal approach which permits removal of the second, third and fourth lumbar sympathetic ganglions with the intervening trunks through an abdominal incision. In sympathectomy of the vessels of the fingers and hands we choose the posterior approach, resecting a portion of the first rib and the transverse process of the first thoracic vertebra on each side, in order to enter the mediastinum and remove the inferior sympathetic cervical and first thoracic ganglions with the upper portion of the thoracic trunk. Occasionally, we can include the second thoracic ganglion through the same incision. When we are unable to include this ganglion we divide all ascending rami to the first thoracic and eighth cervical nerves. We believe this operation to be more thorough than the anterosuperior approach since it is difficult to include all of the vasomotor fibers in the gray rami coming from the second and first thoracic ganglions by the anterior and superior approach.

RESULTS

This study includes a review of 100 consecutive cases from our earliest experience to the present time. There were 89 bilateral lumbar sympathetic ganglionectomies and trunk resections and 15 bilateral cervicothoracic ganglionectomies with resection of the upper portion of the thoracic trunk. Operation was performed in 4 cases of thrombo-angiitis obliterans involving both the upper and lower extremities, which accounts for 104 bilateral operations. Ninety-six patients were males and 4 were females.

The disease occurs chiefly in the fourth decade of life (table 1). The average duration of symptoms was four years on admission. Many of the patients had had toes and extremities amputated before admission. Seven came with the disease so advanced that it was impossible to save extremities by sympathectomy. In the earlier period of investigation we attempted the operation, since we had no method to determine preoperatively the degree of vasomotor spasm (tables 2 and 3).

Table 4 reviews the results accomplished with the complications incident to operation. The neuritic symptoms are not relieved by either medication or sympathectomy. In several instances cutaneous nerve branches were divided with no relief. In two instances, chordotomy was performed with moderate success. The symptoms, undoubtedly, are due to interstitial changes resulting from thrombosis of the blood supply to these nerves. Fortunately, neuritic pains are only occasionally present.

TABLE 4.—*The Results Obtained and Complications Encountered*

	Results

Total . .	104	87	80	76	

In the absence of trophic lesions sympathectomy checked progress of disease in opposite extremity in every instance.

During the early development of sympathectomy in the treatment of thrombo-angiitis obliterans, approximately one patient in seven was sympathectomized. During the last two years the ratio has been increased so that one in three is advised to have sympathectomy. It is further interesting to note that amputation following sympathectomy has been lowered in the last two years through more accurate evaluation of vasomotor spasm and the proper selection of cases for operation.

Sequelae.—Since the vasomotor fibers are intermingled with other postganglionic gray fibers supplying sebaceous and sweat glands, and pilomotor muscles, it is a necessity that these two be divided during sympathectomy as dryness of the skin is thus produced. This dryness is not serious, and if it appears troublesome it can be relieved by the application of hydrous wool fat. The condition serves as an excellent index in determining whether all of the vasomotor fibers have been divided, for if they are not all divided sweating will persist. Lumbar sympathectomy includes postganglionic fibers to the hypogastric plexus, but since these fibers carry inhibition stimuli to the detrusor muscle of the bladder, the musculature of the rectum and contraction stimuli to the internal sphincters of the bladder and rectum, complaints are not made by the patient. This is undoubtedly due to the fact that other fibers carrying similar impulses remain uninterrupted in the presacral nerve and that voluntary control to the external sphincters is not disturbed.

Cervicothoracic ganglionectomy and trunk resection produce Horner's syndrome, but when bilateral the apparent enophthalmos, contracted pupils and the narrowing of the palpebral fissure are not conspicuous nor do they interfere with vision.

ABSTRACT OF DISCUSSION

Dr. A. W. Allen, *Boston:* Our experience in a series of peripheral circulatory disorders at the Massachusetts General Hospital would bear out the remarks of Drs. Adson and Brown in regard to sympathetic ganglionectomy as far as the primary and secondary vasomotor conditions are concerned. Our experience, however, has not been like theirs with thrombo-angiitis obliterans. Perhaps the cases in Rochester may differ from ours somewhat in that they are dealing with the disease in an earlier stage. I am inclined to think that the cases that come into our hospital as bed patients are usually rather advanced. In this advanced group we are not able to find more than one case out of ten with a sufficient vasomotor gradient to warrant an attack on the sympathetic nervous system primarily. The cases of thrombo-angiitis in which we have used this operation have been disappointing. We believe that certain general measures which we have advocated and which are undoubtedly carried out in Dr. Adson's clinic by the peripheral vascular service may play a large rôle in the success of some of his cases, perhaps as large a rôle as the sympathectomy itself. In a chart illustrating a comparative diagnostic procaine hydrochloride block of the sympathetic nervous system, by spinal anesthesia, the upper curve represents a case of primary vasomotor disturbance, Raynaud's disease, and shows a quick rise in surface temperature. In five minutes' time the temperature is elevated approximately 15 degrees fahrenheit. The lower curve is that of a typical case of thrombo-angiitis obliterans, under spinal anesthesia, and it takes, in this case, forty minutes to produce a rise in surface temperature of 9 degrees. I would not consider that a patient who had a vasomotor index as low as 9 degrees would respond to sympathectomy in a satisfactory manner. The important feature in the type of case that we see is the pain these individuals have, the rest pain. A large percentage of them have open lesions; in fact almost every patient submitted to our hospital wards has open lesions of some sort. In these cases we find that sympathectomy will not relieve the pain. Therefore we have had to develop another form of treatment for these individuals. The peripheral sensory nerves of the foot are exposed at about the junction of the middle and lower thirds of the leg. By exposing these nerves under local anesthesia and injecting the larger nerve, the posterior tibial, over a short distance with alcohol, we can anesthetize that nerve for a period of from four to eight months. The smaller nerves, i. e., the anterior tibial, the peroneal and the sural, can best be treated by crushing. The whole foot can be made anesthetic by this method. These patients are absolutely comfortable, and in addition to being able to tolerate dressings, can carry out exercises. This nerve block can also be counted on to produce exactly the same rise in surface temperature or capillary dilatation as is produced by sympathectomy.

Dr. Alfred W. Adson, Rochester, Minn.: I want to say just a word about vascular conditions. It is true that in our original experience the results of sympathectomy were not as good as they are today, because we were attempting to operate on patients who did not have sufficient vasospasm or, rather, sufficient vessels that could go into spasm that we could relieve. Therefore, all our patients are hospitalized, given vaccine and a regional or spinal anesthetic, to determine the degree of vasospasm, and unless we are able to record an increase in skin temperature over the digits twice as great as that obtained by the mouth temperature during the height of fever, we do not operate. In using the spinal or the regional anesthesia the same vasodilatation effects are accomplished and sympathectomy is not employed unless the peripheral skin temperature is raised 3 degrees centigrade. We frequently administer from one to three injections of typhoid vaccine to determine whether the patient is relieved by vasodilatation. If the index is favorable and he is relieved, we perform sympathectomy. We have encountered patients with pain; however, one is not always able to relieve that pain by simply cutting the nerve, since interstitial changes have occurred above the local ulcer. We have done chordotomy in two cases, with only moderate success.

HAVERHILL FEVER (ERYTHEMA ARTHRITICUM EPIDEMICUM)

A CASE REPORT AND BACTERIOLOGIC STUDY

J. BEACH HAZARD, M.D.
AND
ROBERT GOODKIND, M.D.
BOSTON

In January, 1926, Place, Sutton and Willner[1] made careful clinical and epidemiologic studies of a group of cases occurring in Haverhill, Mass. The condition they observed in forty-five cases appeared to constitute a definite entity and was called by them "erythema arthriticum epidemicum." The outstanding clinical features of the cases described were (1) the symptoms of an infection, (2) a rash, and (3) a polyarthritis. Onset was sudden and came with or without chills, with fever and malaise and with or without vomiting, intense headache and prostration. Fever in the beginning often reached from 103 to 105 F. and came down usually on the third or fourth day. The period of eruption commenced on the first to the third day of illness, increased for from one to three days, and lasted then from three to seven days. This eruption consisted of dull red, circumscribed, maculopapular lesions from 2 to 4 mm. in diameter, in general of rubelliform to morbilliform configuration. The rash was distributed mostly on the extensor aspects of the extremities, about joints and in more sever cases across the shoulder girdle and on the trunk or face. Petechial hemorrhages were observed and could be produced by applying a tourniquet. Desquamation was of fairly frequent occurrence. Joint involvement began usually on the

[1] Place, E. H.; Sutton, L. E., Jr., and Willner, Otto: Erythema Arthriticum Epidemicum: Preliminary Report, Boston M. & S. J. **194:** 285 (Feb. 18) 1926.

first to the fourth day of illness. Pain occurred usually in two or more large joints and occasionally in the small joints of the fingers and toes. Active or passive movement of the spine was painful in most cases. Changes varied from almost negligible involvement to marked swelling and redness with fluid. These persisted for three or four days and in some cases beyond two weeks. Variable symptoms were cough, sore throat, bronchitis and delirium. White blood counts ranged from 6,800 to 19,000. Detailed bacteriologic studies of an organism recovered from the circulating blood and from the joints of patients during the Haverhill epidemic were carried out in the Boston City Hospital by Parker and Hudson.[2]

During the spring of 1931, a case of Haverhill fever came under observation in the Fourth Medical Service of the Boston City Hospital. The clinical course of the disease was typical and the specific organism was isolated from the circulating blood on several occasions. The infrequency of this infection, the difficulty in the diagnosis of sporadic cases and the importance of recognizing such cases seem to warrant this report.

REPORT OF CASE

The following is a clinical summary of the case observed by us:

History.—J. C., a man, aged 58, separated from his family and living under poor social conditions, was admitted to the Fourth Medical Service, Boston City Hospital, shortly after midnight, April 23, 1931, complaining of "weakness and pains in the legs." Several months previous to admission the patient "froze" his feet. He noticed afterward increasing swelling of both of them on standing and recurrent numbness in the left foot. Sudden bleeding from the second left toe while walking was noted three weeks before admission. He began to complain of a severe sore throat at about this time. A sensation of tingling and "burning up" in his toes and feet began to trouble him from eight to ten days previous to entrance. About two days after onset of this symptom he bathed his feet in cold salt water in the harbor and noticed many bright red spots on both legs. These lesions became more numerous before he entered the hospital. His appetite had been poor for two weeks, as he felt "generally sick" and abstained often from eating through fear of vomiting. No actual vomiting, abdominal pain or jaundice had occurred. For one week the patient had felt worse and had "trembling chills, just like the malaria shake" at apparently irregular intervals. During the five days previous to admission, he had pains in his feet that were so severe as to limit activity. His knee joints became very painful and at times felt as though "pounded with a club." Considerable spasm resulted if he tried to flex them. His hands began to tingle and burn two days before entrance and became increasingly weak and painful. He had severe pains in his wrists and elbows for the same period of time. He had had many colds all his life and at least one severe sore throat each winter. When the patient was quite young he had what he called rheumatic fever, with swollen, painful joints, for which he was in bed at intervals for a period of nine months. He had had pneumonia twice. Hemoptysis occurred twenty-three years ago, after which he stayed in tuberculosis sanatoriums for three periods and had repeated hemoptyses. The last occurred seven years ago. Loss of weight in recent years was questionable. There was no history of night sweats.

The patient cooked his own meals and ate plenty of fresh vegetables and fruits. He used a considerable quantity of alcohol until prohibition.

Nocturia had occurred three or four times for one year. He experienced no pain or burning except for a slight, rare suprapubic pain on attempting to start the stream. He had had gonorrhea at the age of 20. Syphilis was denied by symptoms and name.

Examination.—He was fairly well developed and nourished and in no apparent distress. The eyes, ears, nose and lips were normal. The tongue showed a small red area from 3 to 4 mm. in diameter, with an ulcerated center, in the middle of the left edge. This was apparently caused by the sharp edge of a carious tooth. There was a marked oral sepsis. The throat was diffusely inflamed, with small tonsils spread out over the faucial walls. No exudate or membrane was present. Small tonsillar and posterior cervical lymph nodes could be palpated. The thyroid was of normal consistency and shape. The chest was long, with a depression in the left anterolateral region and a flare of the costal margin below. Expansion was normal. Examination of the lungs revealed evidence of an old fibroid tuberculosis of the right upper lobe. The heart was normal. The spine showed a slight kyphosis in the thoracicolumbar region. The abdominal wall was somewhat rigid but no tenderness was present. The liver extended 4 cm. below the costal margin and the edge was sharp and hard. The spleen and kidneys were not palpable. The genitalia were normal.

Examination of the extremities revealed the following: Numerous circumscribed bright red, some apparently hemorrhagic macules 1 to 4 mm. in diameter and a few papules were scattered over both legs, most numerous and extensive over the extensor aspect. A smaller number of lesions were found on both arms, on the palmar surfaces of the hands and in the right axilla. Swollen areas of localized redness and tenderness quite definitely demarcated up to about 6 cm. in diameter were present, the largest posterior and a little above the left internal malleolus; others about both knees and over the dorsa of the hands above each carpus. One or more appeared over the middle of both lower legs anteriorly, quite apart from any joint. The ankles, knees, wrists and elbows were quite tender to palpation and passive movement caused pain. A small amount of fluid was present beneath the right patella. No crepitus was evident. The deep reflexes were present. The second toe of the left foot was macerated and infected. The nail was absent and there was evidence of an osteomyelitis of the phalanges. There was sclerosis and tortuosity of the peripheral arteries. Dorsalis pedis pulsations were present in both feet.

Systolic blood pressure was 134, diastolic pressure 80, temperature 100.4 F., pulse 80, respiration 20.

The white blood count on admission was 9,600 per cubic millimeter. The differential count showed polymorphonuclear neutrophils 66 per cent, lymphocytes 27 per cent, monocytes 7 per cent, eosinophils 0 per cent, and basophils 0 per cent. The red blood count was 4,840,000 per cubic millimeter. Hemoglobin measured 77 per cent by the Sahli method. The red cells showed slight poikilocytosis, anisocytosis and polychromatophilia. Platelets were normal. The white blood count reached 10,500 three days after admission but remained below this level the remainder of his stay in the hospital.

Roentgen studies showed an old healed Pott's disease and hypertrophic arthritis of the lumbar spine; elbows and hands, normal; feet, marked arteriosclerosis; left foot, destruction of the terminal phalanx of the second left toe and osteomyelitis; knee joints, hypertrophic arthritis; teeth, multiple caries and periapical infection; chest, old fibroid tuberculosis.

Throat cultures on admission showed Streptococcus viridans, Pneumococcus, and Staphylococcus albus. Cultures of fresh material from the infected toe revealed Staphylococcus aureus.

Blood cultures showed a positive growth of Haverhillia multiformis. The clinical diagnoses made at the time of admission were pulmonary tuberculosis, symptomatic purpura and sepsis of the toe. Typhus fever and Rocky Mountain spotted fever were also considered as possible diagnoses.

Clinical Course.—During the first two weeks the patient had a septic temperature with daily swings from 100 to 103 F. His pulse remained at a level between 80 and 100. Following the third and fourth weeks, during which his temperature was irregular with two rises to 100 and one rise to 101, the patient remained practically afebrile.

On the day following admission the rash appeared to be somewhat faded and within four days it had largely disappeared except for a faint dull pigmentation. The painful and tender areas of induration persisted and several became more prominent, particularly in the region of the right elbow.

---

[2] Parker, Frederic, Jr., and Hudson, N. P.: The Etiology of Haverhill Fever (Erythema Arthriticum Epidemicum), Am. J. Path. **2**: 357 (Sept.) 1926.

Fluid in the right knee joint was noted for several days but was of small amount, so that aspiration was not attempted.

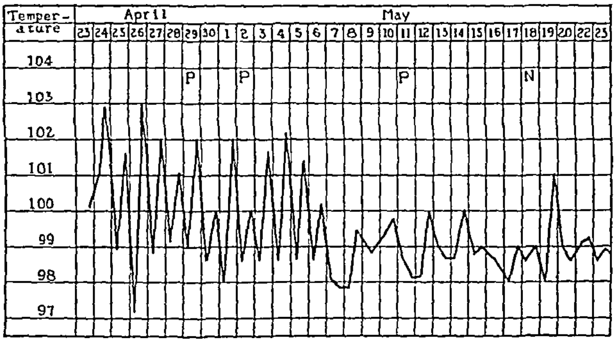
For about three weeks after admission, migratory pain and tenderness with decreasing periarticular induration and swelling persisted. It was five and a half weeks before joint symptoms had subsided. The roentgenograms, taken on admission, of the joints involved during this time, with the exception of the knees, were interpreted as negative.

While in the ward he developed a prominence over the localized kyphos and some soft tissue swelling lateral to it. This was considered as an advance of the old Pott's disease. Further roentgenograms were interpreted as such. The second left toe was amputated three weeks after admission and the wound healed promptly. Orthopedic measures and social aspects of the case kept the patient in the ward several months. He remained, however, symptom free and afebrile.

In summary, the important and characteristic clinical features of the case were a severe sore throat, a rash, pain and tenderness in the ankles, knees, wrists and elbows, and a septic temperature.

BACTERIOLOGY

The organism was recovered from the circulating blood seven days, ten days and nineteen days after admission of the patient to the hospital.[3] The first negative blood culture was obtained twenty-six days after his entrance. Cultures were taken by putting from 5 to 10 cc. of blood from a vein into 100 cc. of plain broth (beef infusion containing 0.1 per cent dextrose). Incubation for seventy-two hours was necessary to produce good growth of the organism. The positive cultures showed darkening of the blood at the bottom of the flask and numerous round yellow balls from 0.1 to 0.3 cm. in diameter lying on the surface of the layer beneath the clear broth. Smears revealed numerous gram negative rods, arranged singly, in small clumps and in short tangled or parallel chains.



Temperature in case of Haverhill fever: *P*, blood culture positive; *N*, blood culture negative.

Morphology.—The morphology of the organism is to a considerable extent dependent on the type of medium used for growth. In favorable mediums it appears microscopically as a rod from 2 to 5 microns in length and about 0.1 to 0.4 micron in width, with a tendency to form short chains, which are arranged in small clumps, tangled together or parallel. Many bacilli from 3 to 4 microns in length and some long, slender bacilli are usually present. Isolated coccoid forms and short chains of cocci are also found.

In less favorable mediums, the polymorphism of the organism is most evident. Besides growing in bacillary form, which may compose the minor portion of the culture, the organism occurs in long fine threads and filaments, which are often quite tangled and measure from 30 to 40 microns or more in length. Long rods may occur in the course of the threads or separated from them. Frequent fusiform spherical swellings in the filaments and rods are characteristically found. These enlargements are sometimes from 10 to 15 microns in thickness. There is evidence in this type of growth of true branching, Y-shaped forms being occasionally found. Some threads stain irregularly, showing many fine granules in the cell body.

On solid mediums, the polymorphism reaches its maximum and the filaments and threads may form 75 per cent or more of the elements. In transplants from solid to liquid mediums, the variation in size and shape is retained to a large extent.

The age of the culture seems to bear little relation to the morphology. Old cultures on favorable mediums may show only a small percentage of the filaments, which appear to be resistant forms.

In smears of material from infected animals, such as the peritoneal exudate and heart's blood, the organisms are found only as short slender rods, from 2 to 3 microns in length.

Staining Reactions.—The organism, as freshly recovered from a blood culture, stains feebly with aniline dyes. It is gram negative and is readily decolorized by acid. No capsules or spores can be demonstrated.

Odor.—No odor is present.

Cultivation.—The optimum temperature for cultivation is from 35 to 38 C. Prolonged incubation kills the organism, five days being the maximum to ensure living cultures. In ascitic fluid broth, the length of life during incubation is less than in other mediums.

The mediums of choice are blood broth, ascitic fluid broth, or fresh clotted rabbit's blood that has been inactivated by heating it for fifteen minutes at 55 C. In ascitic fluid broth the organism grows typically at the bottom of the tube or along the side, with clear broth above. Fluffy balls of organisms from 0.1 to 0.3 cm. in diameter are frequently present. The growth in blood broth is the same as that described in blood cultures. After repeated subculturing, the organism changes the blood to a dark purple color in forty-eight hours. No gross evidence of growth is seen in clotted rabbit's blood, but microscopically an abundant growth of short bacilli, singly and in chains, is found at the end of from twenty-four to forty-eight hours' incubation. The organism does not grow in plain broth and shows only slight growth in hormone broth.

For quick growth of the organism, ascitic fluid broth and blood broth are the most satisfactory mediums. Clotted rabbit's blood is to be preferred for preserving cultures, as the organism is viable in such a medium for as long as four weeks if kept at icebox temperature. Cultures in blood broth die in from ten to fourteen days, and in ascitic broth the organism cannot be consistently recovered after five or six days.

On solid mediums it does not grow aerobically and shows scant growth under anaerobic conditions. An abundant growth is obtained by using a method described by Parker and Hudson. A transplant on solid mediums is placed in a jar with a burning candle. The jar is then sealed off so that it is air tight and the candle flame dies out. The atmosphere so produced seems to be of an optimum physical and chemical composition for growth. By such means it is possible to grow the organism on ascitic fluid agar, on blood agar, and on a medium composed of glycerin, extract of potato and infusion broth with egg yolk added. Loeffler's medium is unfavorable. On solid mediums the organism grows as an opalescent, round, slightly raised colony from 0.1 to 0.3 cm. in diameter. When scraped from the surface, it appears white and mucoid, stringing out and easily rolling off the loop.

---

[3] Credit is due to Miss Marion E. Lamb for first demonstrating the organisms in blood culture.

The organism is fairly sensitive to variation in hydrogen ion concentration. The optimum lies between p_H 7.4 and p_H 8.0.

Oxygen and Carbon Dioxide Relations.—As indicated, the organism is neither strictly anaerobic nor aerobic. The fact that it grows only at the bottom of the tube in liquid mediums indicates its partial anaerobic tendencies. Successful growth on solid mediums only in a candle jar likewise argues for a carbon dioxide-oxygen tension differing from either strictly anaerobic or aerobic conditions.

Sugar Reactions.—Ascitic fluid broth and hormone broth were acidified by the organism and therefore could not be used in determining the sugar reactions. However, a simple medium composed of peptone water (peptone 1 per cent, sodium chloride 0.5 per cent), with 10 per cent ascitic fluid added, furnished a medium rich enough for growth and showed no appreciable change in hydrogen ion concentration. Controls were set up as follows: (1) twelve uninoculated tubes, each containing the medium with 1 per cent of the various sugars used added and (2) one inoculated and one uninoculated tube containing the medium only. With phenol red as an indicator, the control tubes were unchanged after incubation. All changes in the inoculated sugar tubes, except for starch and dextrose, lay between p_H 6.6 and p_H 7.0. In the tubes containing these two sugars the p_H was reduced to about 5.2, as indicated by methyl red. Acting on levulose, dextrose, maltose and starch, the organism formed acid at the end of forty-eight hours, while the p_H of tubes containing inositol, sucrose, xylose, glycerin, rhamnose, lactose and inulin was unaffected. No further change was observed at the end of three, four, six or ten days' incubation. A second series of sugars gave similar results.

Virulence.—In studying the virulence of the organism, white mice and rabbits were utilized. White mice injected intraperitoneally with twenty-four or forty-eight hour cultures died within two to seven days. The amounts used varied from 0.5 to 1 cc. of blood broth or ascitic fluid broth cultures. Postmortem examination of animals dying from two to three days after inoculation was negative. In those surviving from five to seven days, lesions were found in the conjunctiva, pericardium, pleura and mediastinum. A purulent conjunctivitis began on the second or third day after inoculation and was preceded by a period of probable photophobia during which the mouse kept its head buried in the sawdust on the floor of the cage when exposed to the light. The lesions of the anterior mediastinum and pericardium consisted grossly of a collection of purulent exudate. Microscopic examination revealed a collection of polymorphonuclears, serum and some fibrin on the surface of the pleura and pericardium. Short, slender gram negative rods were seen in smears of the exudate.

No joint lesions could be produced by intraperitoneal injection. When 0.3 cc. of a twenty-four hour culture was injected into the joint of one mouse, it survived for seven days and then died, showing typical lesions of the eyes, mediastinum and pericardium. The joint injected was swollen and contained a quantity of thick white purulent exudate. Microscopically, it showed a collection of polymorphonuclear leukocytes and serum over the synovial surfaces. No organisms were demonstrable on smear.

Two young rabbits weighing from 900 and 920 Gm., respectively, were inoculated intraperitoneally with a twenty-four hour growth of organisms in 100 cc. of bouillon, which had been centrifugated and resuspended in 10 cc. of saline solution. Three such injections at intervals of forty-eight hours failed to produce any lesion or symptom.

Agglutination Reactions.—Agglutination tests carried out with the patient's serum and the organism were positive in dilutions of 1:640, during the second week after onset. The bacterium did not agglutinate in normal human serums.

Two strains of proteus X19 failed to agglutinate with the patient's serum in any dilution.

Agglutination reactions carried out with the serum of the patient and B. typhosus and organisms of the B. paratyphosus A and B groups were negative.

Classification.—In respect to the classification of the organism we would concur with Parker and Hudson, who state that it seems to belong in the order Actinomycetales, in the family Mycobacteriaciae and consider it as a new genus, Haverhillia multiformis.

COMMENT

Organisms similar to or identical with the one we isolated have been reported in the literature from time to time in the past, but in most instances the bacteriologic studies are so brief that exact correlation of characteristics is not possible.

Levaditi, Nicolau and Poincloux[4] were the first to describe in detail an organism which, except for minor details, is identical in morphology and growth characteristics with the one isolated in this case. Smears of the organism have been declared identical by Levaditi. Clinically, their case was like the one we have described.

The organism studied by us shows the same characteristics as the one described by Parker and Hudson, and the cases reported by Place, Sutton and Willner presented a similar clinical picture.

Blake,[5] from a case showing the clinical symptoms of rat bite fever (Sodoku) and history of rat bite, isolated an organism which he called a streptothrix but which resembled both morphologically and culturally the organism isolated by us. Schottmüller[6] earlier had isolated a similar organism from two cases, one following a rat bite, the other a squirrel bite. From a case of rat bite fever, MacKie and McDermott[7] obtained from blood culture an organism similar to that described by Blake, which agglutinated in the patient's serum in dilutions as high as 1:1,250. However, several days later by injection of tissue from a lymph node into a guinea-pig, they were able to isolate the Spirillum minus of rat bite fever. They considered the first organism as probably a secondary infecting bacterium. It is possible that the organisms isolated by Blake and Schottmüller from cases clinically resembling rat bite fever were of a similar nature. Other reports of organisms, which in the brief descriptions available seem to resemble Haverhillia multiformis and which were isolated from cases that were clinically rat bite fever, have been given by Ebert and Hesse,[8] Tunnicliffe and Mayer,[9] and Litterer.[10] Tileston[11] observed a bacterium resembling Blake's organism in the blood stream but was unable to grow it from blood culture.

Proof of the etiologic rôle of the organism in our case is based on its isolation from three successive blood cultures and its agglutination in the patient's serum. Furthermore, the clinical resemblance of our case to similar cases from which an identical organism has been isolated gives further proof that Haverhill fever is a clinical entity with a definite bacteriologic etiology.

The source of this infection is unknown. In our case no suggestion could be obtained. Parker and Hudson, and Place, Sutton and Willner thought it might be milk borne, and their assumption was supported by the fact that each patient with the exception of two in the Haverhill epidemic used milk which came directly or indirectly from the same dairy. However, bacteriologic proof was lacking as the organism grew poorly in milk, and all attempts to produce an infection in a cow proved unsuccessful. Levaditi and his co-workers[12] recently isolated an organism that occurs spontaneously in mice and described it as resembling the organism that he isolated from a case in 1925. Inoculation of mice produced gross lesions similar to those produced by us[13] However, a strain of the organism given us by him failed to agree with either the growth or the morphologic characteristics of our organism.

The isolation of a definite organism from the circulating blood of patients having a similar clinical picture establishes "Haverhill fever" as a clinical entity. The organism has such specific characteristics that, even in the absence of an antiserum for carrying out a serologic diagnosis, its identification is possible.

Conversation with a Patient.—Often the busy doctor feels he has no time to spend long hours in conversation with a patient but occasionally such an interview might obviate much suffering, as well as many visits to the office or to the patient's home. Too often this form of approach is replaced by the deftness of craftsmanship, and the use of ingenious tools is substituted for a thoughtful consideration of the problem. If such serious symptoms may arise solely from emotional disturbances, consider, for an instant, the deplorable plight of the poor fellow who has to wrestle, not only with an organic disease, but with his emotions as well. For, I suppose, it is fair to say that no patient suffering from an organic disease, unless his mind be clouded, is free from more or less emotional strain. Whether this depends on the readjustments made necessary by his actual state of illness, or whether it depends on a misinterpretation or improper estimate of symptoms, the emotional strain becomes an actual part of the disease, and has a definite bearing on its course.—Longcope, W. T.: Methods and Medicine, *Bull. Johns Hopkins Hosp.* **50**:4 (Jan.) 1932.

THERAPEUTIC METHODS IN A PSYCHIATRIC HOSPITAL

WILLIAM C. MENNINGER, M.D.
TOPEKA, KAN.

It is a frequent experience to have a medical confrère ask, "What do you do for your patients in the sanatorium?" This question would be asked only about a hospital for patients with mental disorders. All physicians are well acquainted with measures of treatment in the general hospital, but to most of them hospitalization of patients with mental disease means only diagnosis and custody. It is my purpose in this paper to report the therapeutic measures used in a modern psychiatric hospital where my associates and I are attempting to put into practice the principles of dynamic psychiatry.

A patient comes to the hospital not with symptoms, but with problems. What can be done for him? It is not sufficient that he be made physically comfortable; rest and freedom from responsibility alone will not satisfy his psychologic needs. His problems must be studied intensively, interpreted and a solution attempted. This solution can be worked out in two ways: first by the creation of an environment in which the patient can function with more ease than in that from which he has come, and second, by the establishment of a series of scientifically controlled friendships in the course of prescribed therapy.

ENVIRONMENT

From the moment the patient enters the hospital we attempt to provide for him an environment suited to his needs and wishes, i. e., to *him,* rather than to adapt him to the institution. The hospital with all its necessary prohibitions and restrictions, paradoxically, must also permit an opportunity for freedom and an outlet for expression. It must protect the patient from the world and often from himself, and simultaneously create an atmosphere of confidence and reassurance. Above all, it must be a highly organized, efficient institution, and at the same time conceal the organized efficiency and the impersonal institutional air.

Individual differentiation in the manner of the patient's reception and management in the hospital is a large factor in his subsequent improvement. Such individualization is possible only through recognition of the emotional plight of each patient. H. K., for example, a college student, entered our hospital with the delusion that he was in hell; he was tense, mute, fearful and extremely sensitive. In view of this, the nurses were specifically instructed to take frequent occasion to explain his new surroundings in reassuring terms. Extraordinary care was taken to prevent any shock that would aggravate his mental distress. On his first visit to the woodworking shop it was noted by the occupational therapeutist that he shrank from the harsh noises of the saw and the hammer, and that his anxiety was intensified when he was in proximity to one of the workers who was using a crowbar. For this reason basketry work in his room was prescribed until his social reintegration permitted him to return to the workshop.

J. N., to cite another example, a middle-aged minister, came to the hospital loathing himself, "a God-forsaken sinner," unworthy and intolerant of any kindness. He

---

Read before the Section on Nervous and Mental Diseases at the Eighty-Third Annual Session of the American Medical Association, New Orleans, May 13, 1932

was eager to abase himself before everyone and rejected all sympathy because of his strong introjected hostility, and his consequent feelings of guilt and of the need for punishment. No attempt was made to probe into his difficulty at first, and no obtrusive attention was given him. Opportunity was provided for him to work out his craving for punishment in washing walls, splitting wood, polishing floors—anything that gave him an opportunity to serve. He was helped most by a kind of severe kindness which afforded him relief for his acute sense of guilt. Standardized cheer and consolation, a so-called ideal environment, would only have pushed this patient into deeper depression, because it would have intensified his feeling of unworthiness.

H. W., a powerfully built, middle-aged, prosperous farmer, came to the sanatorium believing all was lost, his family starving, hospitalization foolishness and suicide his only solution. Flowers and sunshine, a cheery nurse and reassuring words would have nettled this man and confirmed his arguments that hospitalization for him was "expensive foolishness." Instead of catering to his discontent, his disgruntled arguments and negativistic unsocialness were ignored, and attention was given him only when he entered into activities of the hospital and followed his program. In other words, a premium was put on his cooperation. For instance, at the weekly picnics he would attempt to draw off the doctors and recite his grievances. These attempts were good-naturedly thwarted by putting him at second base on one of the baseball teams composed of doctors, nurses and employes, as well as the other patients. Discovering that he could not obtain attention except by cooperating in the affairs of the hospital, he developed a more conciliating attitude, which eventually made possible his recovery.

Quite a different method was used with H. Mc., who was encouraged to express himself as fully as possible within the limits of safety for himself and others. This patient was excited, talkative and demanding; food and sleep were unimportant in his hyperkinetic state. He asserted, on entering the sanatorium, that he was just in time to receive a spiritual revelation from the God-Head, which must be told only to a priest. The priest came to the hospital although it was late at night. We felt that it was better to give him some harmless outlet for his expansiveness rather than the customary drug sedative. He wrote reams of copy, and finally called for a typewriter on which he transcribed the History of the Bible, and the Epistle of the Thirteenth Apostle (as he called himself).

No discouragement or disapproval clouded this discharge of energy. Care was taken not to give this patient any invitation or opportunity to follow his conscious desires to do violence or to escape, which were obviously in conflict with his unconscious desires to be held in restraint. He sometimes begged for this restraint, as, for example, when during intravenous treatment he would ask an attendant to hold his arm lest he harm some one. As much freedom as possible was permitted him to carry out his wishes, with such modification as this supporting restraint to his nearly obliterated super-ego made necessary.

Thus, instead of supplying a uniform environment, which seems comfortable to us as healthy persons, the hospital furnishes each patient with an environment that he can accept with greater ease and comfort, because it allows him to express himself at a simpler level than that of the reality from which he has taken flight in his illness.

In providing him with this tolerant, friendly haven, we find that the less the patient is reminded that he is separated from the outside world by prohibitions and restrictions, the more his readjustment is expedited. Consequently, as soon as the patient's progress permits, he is graduated from the hospital to the sanatorium, a separate building, where he is free from all restrictions except the friendly supervision of doctors and nurses.

It is not our purpose, however, to maintain the mentally sick patient in this individualized environment indefinitely. The process of recovery requires that he gradually win his way back until he is able to leave the artificially created atmosphere and reenter the world of reality. He might be content to rest forever in this (for him) comfortable state were it not for the emotional response which he develops toward the persons who provide this haven for him and who minister with such understanding to his wishes, conscious and unconscious.

SCIENTIFICALLY CONTROLLED FRIENDSHIP

This emotional response, which we think of as scientifically controlled friendship, we regard as the chief factor in the process of recovery. The hospital building and all the materialistic armamentarium are of little importance as compared with the personality relationships that exist between the patients and the members of the staff. Every doctor is familiar with the part that confidence plays in the treatment of his patients, and he is aware also of the influence, adverse or favorable, of relatives and friends on his patients. This familiar principle has been capitalized, elaborated and greatly reenforced by making it a matter of study and practice for not only the doctors and nurses but every employee of the institution. Every member of the personnel is interested not only in carrying out his particular routine function, but also in contributing something personal to this ruling principle. For example, the chef, who, in addition to being a good cook, is an expert tennis player, supervises the maintenance of the tennis court and plays regularly with the doctors and patients. The girls who work in the kitchen and dining room are among the best of the baseball players, and hurry through their work to participate in games.

This attitude on the part of the employees is secured, first, by extremely careful selection. Throughout the entire institution the employees must be of a superior type, people with whom the patients can associate without reluctance. Greater stress, however, is laid on the training of the employees after they become associated with us. Graduate nurses rarely obtain in their general hospital training an adequate understanding of the psychologic problems involved in the treatment of mental illness. Hence, education in psychiatric principles and the psychodynamic point of view is even more important than their general hospital training in developing the technic of tactful understanding of the delicate and subtle requirements of psychiatric nursing.

This process of education continues for the nurses and attendants as long as they are employed in the institution. An average of one hour daily is allowed them to attend lectures, conferences and study groups, and to prepare notebooks and to read and review selected books and periodicals from the hospital library.

The educational program includes training for not only the nurses and attendants but to a somewhat less technical degree all employees, including the kitchen help and office force. In addition to didactic work in psychiatric principles, these persons as well as all other employees attend regular conferences which integrate policies and activities of the group. As a result of this continued and intensive training, the whole staff of the institution is permeated with this spirit of cooperation and sympathetic insight into the aims of the hospital and the methods of carrying them out. They are thus prepared to apply the therapeutic principle of scientifically controlled friendship to the patients.

THE DAILY SCHEDULE

To be most effective this principle must be carried out in a systematic way, with specific application to the needs of each patient. To insure this, a schedule of assigned activities is written out and given to each patient at the beginning of each week. This not only informs the patient that he is being given individual consideration, but also maintains a continued plan of prescribed therapeutic attack. Preeminently, however, it gives opportunity for successive personal contacts through the prearranged scheduling of the various therapeutic tools of occupational therapy, recreation, physical therapy, reading, music and other creative efforts, rest, psychotherapy, study groups, etc. The friendly relationships which the patient forms in the course of his schedule transforms this daily plan from a progression from one unrelated unit of treatment to another into a continuous process of treatment facilitated by varied occupations. For example, Mary B's schedule on Wednesday at 10 o'clock reads "Occupational therapy—sewing on a quilt"; but Mary reads into this something far more personal and satisfying, because her doctor, who is interested in ships, drew for her pictures and diagrams of the many kinds of sailing ships. These Mary painstakingly traced on cloth of her own choosing and cut out white sails and appliquéd them on a blue sea with infinite care and devotion. This project was artistically conceived and executed by the patient as a gift for her doctor. The work began while she was lying listlessly in her bed, depressed and weeping, but as the quilt progressed, it necessitated contacts with other people; she must choose materials and use the sewing machine; finally she began to enter into the other activities of the hospital. Thereafter, her progress was rapid.

This whole plan of treatment is a continuous form of psychotherapy. It depends initially on the physicians' understanding of the patient's conflicts gained through frequent personal conferences. These interviews are not the casual contacts established in ward rounds, but are scheduled appointments.

The value of friendliness, kindness, personal attention and encouragement are recognized intuitively by almost everyone, but their scientific application as therapeutic tools is surprisingly rare. In our experiments and investigations we have attempted to carry this principle into all departments and to animate the patients' work with its purposive stimulus.

RECREATION

Organized recreational activity is a particularly effective medium for the application of this method of treatment. The director of recreation, who gives his full time to this work, skilfully leads the patient to express an interest in some sport or hobby which is utilized in developing a friendship, then in drawing the patient into some activity and finally in bringing him into a social situation in which he cooperates with other players. Thus, by an indirect method of free play, the patient is enabled to suspend temporarily, in varying degrees, his own intrapsychic conflicts and to accept a form of reality.

Our experiences, as well as the reports of other hospitals, have led us to believe that the chief therapeutic value of athletics is the social value, especially in a hospital where men and women mingle in games and contests. This adds a powerful socializing influence not possible in institutions limited to one sex or where the sexes are kept separate.

We have found it satisfactory to have both men and women play together on the indoor baseball teams which include practically every patient and every member of the staff. Although this is a group activity, its benefits can be specifically adapted to the individual. In the case of H. K., for example, baseball afforded him an opportunity to show some superiority. This patient's fantasy material showed that he had taken refuge in flight from reality because of his profound feelings of inferiority. He had visions of himself as God, the All-Powerful. It was discovered that although he had only one hand, he could catch more balls and knock more home runs than almost any other player. In this situation, H. K. was able to excel in reality and had no need to fantasy himself as successful.

Depending on their condition, the patients are encouraged to become captains of teams or directors of activities. The manner in which the responsibility therapy is applied is shown in the case of E. R., an apathetic, depressed hypo-active girl, who irregularly and without interest took part in the morning setting-up exercises. She was delegated to lead them, and immediately sought a book of instructions in the library, asked for suggestions from various members of the staff and assumed an active, aggressive leadership.

Many similar examples of how group recreation is applied to the individual problem could be cited. In order to interest every patient, a wide diversity of activities, including golf, tennis, croquet, shuffleboard and volley ball as well as many indoor games and contests, are scheduled. Swimming has been prescribed to overcome muscular rigidity, incoordination and negativism, with gratifying results.

In addition to the parties which are specifically prescribed, a patients' club functions weekly with a program consisting of a presentation of some interesting topic by one of the patients. This may be the elaboration of a current event, perhaps a description of the patient's business, occasionally the presentation of a hobby, a review of a new book or perhaps a musical program. This necessitates a certain amount of integration and membership and is considered a privilege. In the same way, outings, attendance at church, picture shows, lectures or concerts are prescribed as indicated by the individual's needs and preferences.

READING

Our experience with the prescription of reading extends over the last year. We are accumulating some data in this virgin field of therapeutics and are conservative in attempting to estimate results to date. The cardinal principle is the prescription of specific reading material rather than letting the patient pick up something at random or, as is more often the case, to do no reading at all. In a few instances the patient is asked to write a review of the assigned material. The books are chosen for their interest to the patient from what we know of his background and hobbies, and if possible for the therapeutic content. We have experimented with a good many types of magazines, fiction, biography, poetry and to a considerable extent with mental hygiene literature.

For many weeks after her admission, a hypomanic patient repulsed our psychotherapist, regarding his attempts to gain her confidence as a repetition of what she called the insincere attitude of her double-crossing relatives. Finally, he brought her a copy of Moby Dick and discussed with her at some length his interest in the story and its significance as an allegory. A few days later with self-deprecating bravado she gave him a longhand copy of the chapter called "The Lee Shore," with the explanation that she had awakened early one morning and copied it because she liked it so much. In that eloquent chapter she found a sympathetic description of her own flight, which relaxed her resistance and allowed a positive transference to begin.

OCCUPATIONAL THERAPY

Occupational therapy is almost as old as psychiatry, but much that has gone under that name has little or no therapeutic value. Work in the ward, including the care of the rooms, kitchen and laundry, and farm work may have a therapeutic value in isolated cases, when individually prescribed, but in general their use is of advantage only to the hospital administration. By no stretch of the conception can occupied time be considered as synonymous with occupational therapy.

The occupational therapist in the hospital follows the same procedure as was described for the recreational director, in first interviewing the patient at the earliest opportunity to determine his interests and capabilities. Then after consultation with the physician, the prescription is written for the patient, but it is through the personal influence of the therapist and the physicians that the patient is brought to attempt the work. We believe that the benefit to be derived from handicraft, aside from the socializing influence of the workrooms, is the opportunity of expression it affords the patient. This must be individualized to suit the requirements of each one: the schizophrenic patient finds in his work a contact with reality; the manic patient uses it as a propitious outlet for the discharge of energy; the introspective patient is given an opportunity for extraversion, and the sadistic patient works out with tools his antisocial impulses. We have found that it is of tremendous value to a patient with fragmented psyche to produce something, which, trivial as it may be in itself, represents to him a valuable personal contribution.

To recognize this, the occupational therapist must have a knowledge, not only of arts and crafts, but also of the psychiatric point of view. The physician too often regards the occupational therapist as just another attendant, and her teaching as an unimportant form of pastime for the patients. He should not only lend his active support, but should inform himself of the field, so he may intelligently prescribe specified types of occupation and evaluate their success in his patients.

MUSIC

Our experience with music as a part of the treatment has led us to conclude that in many instances it is not applicable (certain people have no musical interest or ability) and in other instances it is certainly detrimental (in hypomanic states and certain depressions in which the stimulated associations are too painful). On the other hand, it has proved to be beneficial to the majority of our patients through the opportunity it affords for self-expression and socialization in fireside group singing, instrumental music, quartets and solo work. This benefit has been most noticeable in persons convalescing from cyclothymic states, in reversible schizophrenic patients and in some psychoneurotic patients. In several instances we have provided instrumental training for unsocial schizoid persons, with improvement in their mental status and a fair degree of success in their musical efforts.

SPECIAL ACTIVITIES

The close personal relationships which the patient forms and the awakening interests which arise from them often result in rather novel departures from the customary procedure. The benefit derived from these special activities in individual cases more than warrants the additional supervision and planning which they require from the personnel. Provision, for example, is often made for patients to attend public lectures and entertainments, to organize nature study groups, to study French or stenography. In several instances, arrangements have been made for patients to take class work at a local college or the high school. Members of a boy scout troop in the city have been very cooperative in including some young male patients in their activities and in encouraging them to participate in swimming, boxing, etc. A college student has been employed to devote several afternoons a week acting as a companion and observer to a schizophrenic, unsocial, erratic lad about his own age.

Creative activities, such as sketching, painting and writing, are encouraged, with gratifying results, therapeutically if not always artistically. The preparation of a marionette theater has lately occupied the attention of a large proportion of the patients.

PSYCHOTHERAPY

All of the procedures described, rightly administered, gain their ends because of the psychiatric principles involved and are therefore a kind of psychotherapy. This, however, does not mean that more systematic technics of psychotherapy should not also be used. It is my conviction that every patient in a psychiatric hospital is capable and deserving of psychotherapy of some sort. For a few, the standard procedures of freudian psychoanalysis are desirable.

PHYSICAL THERAPY

These principles of treatment do not make it possible to dispense with the well established technics of physical, chemical and electrical therapy. Rather, they make these more effective, for the psychologic effects of the personal attention and physical manipulation are probably more beneficial than the physiologic effects.

Physical therapy is an assigned prescription for every patient daily. The modern psychiatric hospital is equipped with a hydrotherapeutic department for sedation, stimulation and elimination; with diathermy for the treatment of paresis; with provision for special dietary methods, and with necessary drugs, and the usual medical and surgical supplies and instruments. But chief reliance must not be placed on these, for the treatment of functional mental illness by physical devices is as illogical and unscientific as it is experientially futile.

SUMMARY

It has been the purpose of this paper to describe the modern hospital treatment of mental illnesses, a treatment based on the understanding of the psychologic conflicts of the maladjusted patient. The method consists in the establishment of an environment adapted to the individual patient's needs, which will give him greater comfort and freedom of expression than that from which he has come, and in the arrangement of a connected succession of personal contacts with understanding persons with whom the patient develops rapport in the course of a daily schedule of therapeutic activities. This relationship is capitalized in encouraging the direction of the patient's energies into more productive channels and, finally, in bringing about the carefully graded separation of the patient from his dependence on these aids and the facilitation of his return to the home environment by improved understanding.

ABSTRACT OF DISCUSSION

Dr. F. Garm Norbury, Jacksonville, Ill.: If something were not wrong with the ability to adapt to home, business and social life there would be no occasion for entrance for treatment in this field. The underlying situation and the precipitating cause in association with the physical condition demand first attention. Then, based on these conclusions, comes the plan for treatment. Perhaps this feeling may be best stated thus: A knowledge of the mental mechanisms involved plus the embodiment of the principles laid down in Weir Mitchell's "Doctor and Patient" and Peabody's "The Care of the Patient" have *meant more in formulating such a plan than anything else.* The organization carrying out the details of such a procedure is a most important part of such management. Close clinical supervision coupled with nursing experience means much for individualization. This is one of the main justifications of a private sanatorium. The opinion may be expressed that the apparently casual yet well considered conversation on the part of an experienced masseur or masseuse during a massage is often more valuable than the actual manipulation itself. The psychiatrist must know just what the situation and needs are with each particular case, how much has been accomplished and what direction the next approach must take. He must have acquired the art of approach and suggestion. He can then make use of the various measures described by Dr. Menninger. Knowledge, art, tools—these three cannot be separated when therapy is considered. Grasp and insight in the psychotic, poise and well considered emotional response in the neurotic come from the establishment of normal chains of thought and of normal outlook. They come from the development of or restoration of confidence; from the ability to see things as they are, to meet things as they exist. The actual coming is more often the result of personal effort and conversation by the physician than anything else. Any type of therapeutic aid which he can employ to help in the preparatory stage is of value and should be utilized in the way Dr. Menninger has described.

Dr. Thomas J. Heldt, Detroit: Successful response to the therapeutic aids to which Dr. Menninger has called attention is largely dependent on individualization and personalization, not only on the part of the patient but also on the part of the physician and other hospital employees. The importance of these aids is such that they may well be extended to general hospitals in which nervous and mental patients are treated. I have had some nine years of experience in applying to patients in such a general hospital most of the therapeutic measures mentioned. I can corroborate their effectiveness, so clearly outlined in the cases reviewed by Dr. Menninger. I would emphasize that in the carrying out of these therapeutic aids repeated call is made on lay personnel, some trained, some semitrained, and still others largely untrained. In this regard I have found it advantageous to arrange ten-minute explanatory talks daily by the floor physician to orderlies and maids and to others of the lay personnel mentioned. I have found also that the bringing of a nervous and mental patient into a general hospital is in itself an environmental setting of importance. The helpfulness of such setting is reflected not only in the favorable reactions of the patient but also in the newly conditioned responses of the hospital superintendent, the lay personnel and our medical associates.

Dr. George S. Johnson, Denver: I should like to direct attention to the point Dr. Menninger made about the individualization of the patient. In general hospital experience one finds that the patient comes into the hospital and at once feels he has a physician who is attending him, but in the psychopathic hospital and in the psychiatric institution the tendency is to feel that he is in the hospital for the time being and is merely waiting for the time when he can go out, and that recovery is a matter of time. Dr. Menninger has called attention to the systematic application of the contact he makes in the hospital. I find in the hospital in Denver that the explanation of the dynamic concept not only to the patient but to the entire personnel is of great value in creating that which Dr. Menninger has brought out in his paper.

LABORATORY INVESTIGATIONS AS AIDS IN OTOLARYNGOLOGIC DIAGNOSES

L. W. DEAN, M.D.
ST. LOUIS

The cytologic examination of the nasal discharge is, in my judgment, an important procedure with every patient with a nasal lesion. I should feel that my examination was incomplete if this had not been done. The cytologic examination of the discharge from the ear, while not so important, has a distinct advantage. If on examination of the nasal discharge it is found to be almost all mucus with very few cells, that means one thing; if the fluid contains practically no mucus, as in cerebrospinal rhinorrhea, that would suggest another thing. The presence of many polymorphonuclear neutrophils in the discharge taken from the neighborhood of the ostium of the sinus indicates infection. Even to a layman the presence of pus cells will mean something. When red blood cells are found they have clinical significance. The presence of degenerated epithelial cells without any blood cells is of decided clinical significance.

Certainly it is of great importance to have information regarding the number of eosinophils present in the nasal discharge. While the increase in the eosinophils does not necessarily mean an allergic condition or the absence of eosinophils exclude allergy, the presence or the absence of these cells is suggestive. Only a few cases that we have seen with a marked nasal eosinophilia have proved not to be allergic. Many cases in which there has not been an increase in eosinophils have been found to be allergic. Repeated examinations of nasal smears will often reveal a marked increase in the eosinophils which was not present on former examinations.

The cytologic examination of the discharge from the ear should be made at the time of myringotomy if possible. When macroscopic blood is secured at myringotomy, a cytologic examination may reveal many polymorphonuclear neutrophils. The presence of these cells in the blood indicates an otitis. The state of degeneration of the polymorphonuclear neutrophils found in the discharge from the ear suggests the severity of the infection. The greater the degeneration of these cells, the more active is the process as a rule.

In a large number of patients with purulent otitis, many eosinophils have been found in the nasal and nasopharyngeal discharge, but as yet we have not discovered a discharge from the ear with many eosinophils.

The discharge from the nose is examined by taking a cotton carrier and touching the neighborhood of the ostium of the sinus. The material adhering to the cotton is spread on a slide so as to leave strands of mucus

---

Read before the Section on Laryngology, Otology and Rhinology at the Eighty-Third Annual Session of the American Medical Association, New Orleans, May 11, 1932.

on the slide, if some are present. The strands of mucus in the nasal discharge act like fish-nets and collect the cells that are present in the discharge. Similar preparations are made from the ear, the discharge being taken from the myringotomy wound immediately following the incision of the drum head or from a perforation in the drum head.

The film on the slide is gently fixed with heat, the slide is flooded with Wright's stain for one minute, an equal quantity of buffered distilled water is added for three minutes, and the slide is washed with distilled water and air dried and is ready for microscopic examination. It is important to know that the Wright's stain is perfect. This stain deteriorates in a few weeks. Only stain that is known to be good by actual test should be used; otherwise, the results will be disappointing.

Fluid that is aspirated may be examined in the same way, or it may be examined as are the washings from the sinuses and from chronic discharging ears. The fluid secured is placed in a container and thoroughly shaken in order to separate the cells from the strands of mucus. The material is then placed in a centrifuge tube and centrifugated for a few minutes at a slow speed. This precipitates the mucus threads, but does not throw down the cells. The fluid is decanted, placed again in a centrifuge tube and centrifugated at a rapid speed for two or three hours. This precipitates the cells as a compact mass in the apex of the centrifuge tube. The fluid is drawn off and the precipitated mass hardened with formaldehyde. Before the fluid is placed in the tube, a flattened wire bent to fit the bottom of the tube is inserted so that the mass is in the bend of the wire. After the mass is hardened it can readily be removed from the tube by means of this wire. It is then mounted in paraffin and sectioned and stained as tissue.

It has happened that in a case of an unsuspected malignant condition in a maxillary sinus, groups of cancer cells were found by this method. This made the diagnosis of carcinoma.

When the washings in cases of otorrhea are studied, some of the material precipitated should be examined under the microscope for cholesterol crystals before it is hardened. The presence of cholesterol crystals plus fatty degenerated epithelial cells makes the diagnosis of cholesteatoma. This procedure often reveals the presence of cholesteatoma which was not found by examining the fluid without centrifugation.

The chemical test for cholesterol on the discharge from the ear in chronic purulent otitis media is still an uncertain procedure. The fluid from acute otitis gives the reaction. The exact quantitative test indicative of cholesteatoma has not been determined. Chemical tests have the advantage in that they determine the presence of amorphous cholesterol as well as the crystals.

Roentgen examination of the nose and ear has become an important factor in diagnosis. My impression is that roentgen examination has been at least sufficiently emphasized. To me a thorough clinical history and an excellent examination are far more important than the roentgen procedure. At any rate, in nasal sinus disease one is not justified in making a diagnosis of an infection of the sinuses because the roentgenogram shows that the lining of the sinus is thickened. The lining of a sinus is often thickened because of an allergic condition, and in the early stages of nephrosis the thickening is due to a pure edema which is part of the generalized edema of the patient. Roentgen examination of the nasal sinuses together with a cytologic study of the discharge should give definite information. Certainly, many patients who were thought to have infected sinuses requiring radical operation have been treated successfully by conservative treatment when the cytologic study plus the history has shown that a thickened lining was an edematous process and not an infected membrane.

In infants and young children I have the roentgen examination made first. This is done to determine whether or not a given sinus is present, and, if present, whether or not it has clinical significance on an anatomic basis. Years ago Dr. Mosher remarked that nasal sinuses in children were precocious. In older children and in adults roentgen examination is of the greatest help in clearing up obscure points regarding pathology. It should be made only after the securing of a thorough history and after a careful clinical examination. For many years some of us did laryngologic work without the use of the x-rays, and by means of a good history plus a thorough study of the case we made an exact diagnosis. Perhaps our patients were better off than those who are now operated on, because an x-ray picture shows a slight thickening of the lining of the sinus. At any rate, the x-rays should be used to clear up those points in diagnosis which are not definite after a thorough clinical examination has been made. The roentgenologist should have before him the history and clinical findings and a statement of the information that is desired.

Certainly x-ray pictures of the maxillary sinuses are bound to be misleading unless their interpretation is helped by a good history and a clinical examination.

Differential examination of the blood, particularly with the Schilling method in otolaryngologic cases, is a procedure that should be done by experienced persons. The recognition of cell types and the evaluation of the differential blood count require technical as well as clinical experience. A proper differential count of the blood may in itself make the diagnosis. In the study of infections, it may be the deciding factor as to whether operation is necessary or whether it should be deferred.

It should be remembered that the otolaryngologist sees not only cases of agranulocytosis, but rarely cases of infectious mononucleosis and more commonly cases of lymphatic reactions following infections about the nose and throat. He also sees cases of myeloblastic leukemia, aplastic anemia, myelogenous leukemia and lymphatic leukemia. The early symptoms of these diseases may manifest themselves first in the throat.

Ulcerative as well as hemorrhagic lesions in the nose and throat may be only symptoms of a primary blood dyscrasia, the diagnosis of which is possible only by a careful differential blood count.

Agranulocytosis is a disease characterized by marked depression of the granular elements in the blood with marked leukopenia. There are various theories as to its cause, and one is that it is a primary disease of the bone marrow with a special predilection for the glandular elements. The diagnosis of this disease can be made only by careful differential studies of the blood. The clinical picture of this disease may not differ from that of myeloblastic leukemia, the main difference between the two being made on a differential count of the blood, which in myeloblastic leukemia shows myeloblasts, whereas in agranulocytic angina there are no blast cells. In the same way, the differential diagnosis between a lymphatic reaction secondary to infection about the nose and throat and lymphatic leukemia is made by the finding of lymphoblasts in lymphatic leukemia.

Aleukemic lymphadenoses and myeloses can be differentiated only by careful differential counts of the blood. It requires experience to recognize these early cells as lymphoblasts and myeloblasts. In aplastic anemia, the earliest symptoms may be referable to the throat. It is characterized by marked diminution in all three blood elements: leukocytes, platelets and red cells.

Often a diagnosis is made of monocytic angina with a temporary rise in monocytes together with a rise in lymphocytes. This does not constitute a diagnosis of monocytic angina, and really represents only a temporary rise in monocytes, which is not uncommon with infections in the tonsils, and the lymphatic reaction persists longer than the monocytic reaction.

Probably the greatest value in the Schilling differential count of the blood for the otolaryngologist is the study of infections. The interpretation and evaluation of the degree and seriousness of the infection can be best measured by the differential count of the blood. Prognosis is closely associated with differential changes in the blood. An increase in the Stabkernige cells in the Schilling differential count of the blood is a degenerative picture, and in infections of the nose and throat is not of serious moment in itself. With an increase in the severity of the infection, younger cells, so-called Jugendliche cells, appear in the blood stream and classify the picture as regenerative. With further progression of the infection, more serious regenerative pictures are seen, with the presence of myelocytes. When myelocytes are found in the course of an infection, they are always to be considered seriously. The time to operate may be decidedly influenced by a differential count of the blood. The progress following operation or other treatment can be most accurately determined by the differential count of the blood. The onset of complications can also be measured accurately.

In the diagnosis of tuberculous lesions of the nose and throat, the Schilling differential count of the blood, together with the subcutaneous tuberculin test, is invaluable. An increase in the number of Stabkernige cells may be present in any infection and is always present in active tuberculous lesions. Syphilitic lesions, unless secondarily infected, do not show an increase in Stabkernige cells; neither do tumors unless they are infected. In a suspicious tuberculous lesion of the nose and throat, with an infectious blood picture as evidenced by an increase in the number of Stabkernige cells, the blood picture can be modified by the use of tuberculin.

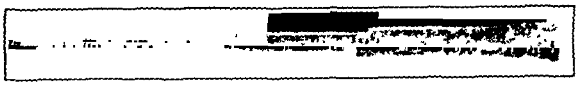

Fig. 1.—Glass sleeve swab protector for collecting nasal smears in position for use. The whole is inserted through a nasal speculum into the nose. The flare on the end of the outer tube protects the inner one from contamination. C. S. Linton.

After the injection of 10 mg. or less of old tuberculin into a tuberculous lesion that is not healed, there is an increase in the number of Stabkernige cells in twenty-four or forty-eight hours, or a drop in lymphocytes. A negative reaction of the blood following 10 mg. of old tuberculin excludes tuberculosis.

As I view it, the exact determination of the blood findings is a procedure that requires experience, both in making the differential count and in its interpretation, and should be done by one trained in hematology as well as in clinical medicine. While the otolaryngologist may be able to make a fairly accurate differential count of the blood in most of the ordinary infections, yet my own judgment is that when it is necessary to depend on blood findings to differentiate between the blood dyscrasias and infection, to determine the exact significance of the blood picture in severe cases of sepsis, to differentiate between lymphatic reactions and monocytic anginas or infectious mononucleosis or to determine the presence of active tuberculosis, one should depend on an expert for the examination of the blood.

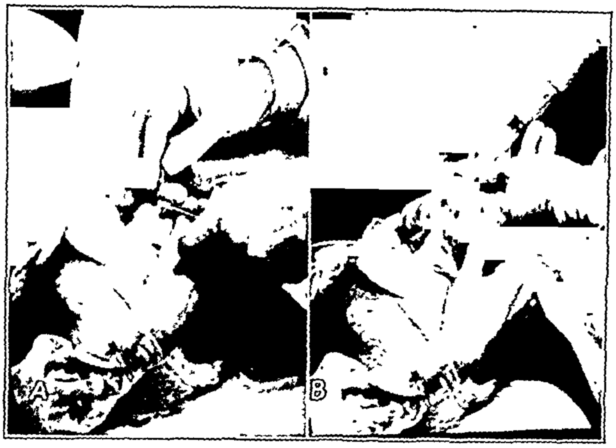

Fig. 2.—*A*, trocar inserted through the inferior meatus into the maxillary sinus. *B*, a Luer syringe attached to the trocar, containing physiologic solution of sodium chloride.

The examination of material secured at biopsy should be made by the surgeon who is in charge of the case. The surgeon should be well grounded in pathology. If he has this knowledge, he should be best prepared, because of his clinical conception of the case, to make the diagnosis. Often in diseases of the larynx and even in lesions of the tongue, when they are malignant, the piece secured at biopsy will not show the malignant process. The surgeon would not be led astray by the microscopic picture, but should be guided by the results of his history and examination and make a second or even a third biopsy before coming to a definite conclusion.

If a person is not sufficiently grounded in pathology, he should look at the tissue with a pathologist and give to him the benefit of his clinical knowledge of the case.

In making bacteriologic studies in infections of the ear, nose and throat, it is important to secure the material for investigation in a proper way. The material from the ear should be secured, if possible, at the time of myringotomy. The next best time to secure the material is when and if an operation is performed on the mastoid. Routine cultures of the pus in mastoid cavities give a large percentage of negative results, especially in infants; consequently, pieces of tissue for culture should be sent to the laboratory in addition to the cultures made from the discharge. The specific organism responsible for the infection should be present in the tissues. Such a procedure will almost always give a positive result if the bacteriologic examination is thorough. In the same way, the lining of an infected nasal sinus is the best material from the sinuses for bacteriologic study.

In work on the nose and throat it is advisable to have available to the resident staff an incubator so that the cultures may be prepared immediately.

The objection to making cultures from discharges from the ear after myringotomy or spontaneous perforation is that the contaminating organisms often overshadow and prevent the finding of the real etiologic factor.

It is common to find type III pneumococcus at the time of myringotomy and then to fail to find it in repeated examinations made on the discharge from the ear, and then to find it again at the time of operation on the mastoid.

In making a bacteriologic examination of the nose, it is necessary to use a double glass sleeve containing the cotton on a probe (fig. 1) in order to get the culture only from the point that it is desirable to study. If a cotton swab is inserted into the nose through the nasal speculum, it becomes contaminated before it reaches the area to be investigated. The examination of the middle meatus of normal noses in midsummer by such a procedure has shown 80 per cent of them to be sterile. This finding can be secured only if a double glass sleeve or some protecting mechanism is used with the cotton carrier on its way in and out of the nose.

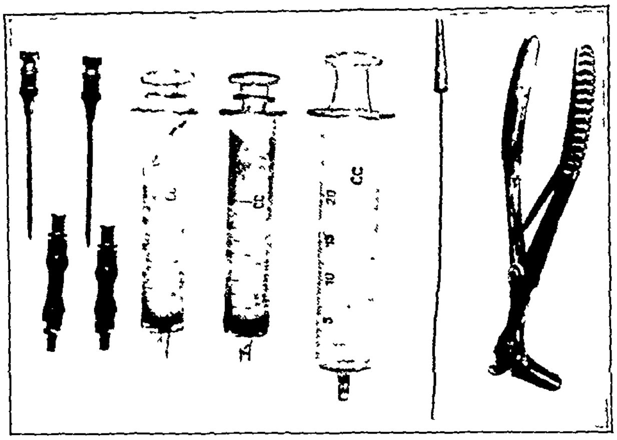

Fig. 3.—The trocar and syringe used in obtaining fluid for examination.

In making cytologic and bacteriologic studies of the nasal sinuses, it is necessary to aspirate the contents of the sinus or, if a fluid is not secured on aspiration, to introduce into the sinus a little sterile physiologic solution of sodium chloride, swish it around in the sinus and then aspirate it. The fluid thus secured is used for study. A good method of doing this in infants and older children is to insert a trocar through the inferior meatus into the maxillary sinus under gas anesthesia (fig. 2 *A*). When this is done the operator should have before him in an illuminated box the x-ray picture of the sinus in order to know the exact relationship of the floor of the maxillary sinus to the inferior turbinate. After the trocar has entered the antrum, the stylet is withdrawn. Using a rubber connection, a Luer syringe containing about 4 drachms (15 cc.) of physiologic solution of sodium chloride is attached to the trocar (fig. 2 *B*). A part of the physiologic solution of sodium chloride is injected into the antrum and then aspirated into the barrel of the syringe. Frequently pus so thick that it will hardly pass through the cannula is aspirated. (Figure 3 shows the trocar and syringe used in this procedure.) The material thus secured from the maxillary sinus is not contaminated by the contents of the nose and serves the excellent purpose of furnishing material for bacteriologic and cytologic study.

Search must be made in all cases of infection of the ears, nose and throat for both aerobic and anaerobic organisms. The search for anaerobic organisms occasionally gives unlooked for results.

When acid-fast organisms resembling Bacillus tuberculosis are found in the material from the ear, it is necessary to make injections into guinea-pigs in order to determine definitely whether or not it is Bacillus tuberculosis. Even if this organism is found in the discharge from the ear, if the patient has active pulmonary tuberculosis it may not be a case of tuberculous otitis, but the organism may be there as a contaminant.

Blood cultures and cultures from the spinal fluid are often indicated. In cases of suspected otitic or laryngologic sepsis, the agglutination tests for typhoid, paratyphoid, melitensis, typhus, meningococcus and tularemia will occasionally show that the infected ear is not responsible for the serious illness of the patient.

In the same way a careful search for malaria in the blood in a case of suspected thrombophlebitis in a lateral sinus will rarely give positive results.

The Kahn precipitation test and the Wassermann complement fixation test should be used as routine measures.

ABSTRACT OF DISCUSSION

Dr. Harris P. Mosher, Boston: I have found the Schilling index valuable in interpreting the course of infections and in evaluating them. It often hastens operative intervention, and it frequently helps in making a prognosis. Since the advent of agranulocytic angina, the differential blood count has come to the front. It alone makes the diagnosis. But long before this disease was described there were the leukemias and various blood dyscrasias which show their first signs in the throat. I have a feeling that any throat condition which is not definitely suppurative, and in which biopsy is not promptly positive, calls for a differential blood count. From the patient's standpoint, I think the physician who is not in intimate touch with a laboratory should take a routine culture in his throat cases and perhaps in every case make a differential blood count. Dr. Dean said nothing about epidemic sore throat. The laboratory a few years ago isolated the organism of this disease and has lately made a serum available. This is the only hope that has appeared in this dread disease. Dr. Dean's statement that one should not depend on swabs for detecting bacteria but should hunt in tissue specimens interested me especially. He said that if one does not find the bacteria it is because one does not hunt long enough. This points a way out. It may mean a solution in cases of infantile diarrhea associated with so-called mastoiditis.

Dr. Burt R. Shurly, Detroit: Dr. Dean's method of obtaining specimens for cytologic and bacteriologic studies without contamination is deserving of practical application in the office and in the hospital. The early knowledge of the culture findings, the chemical changes in the blood, the roentgen study and the study of the nasal discharge greatly influence the early choice of proper therapeutic measures. But with these laboratory aids easy of access it is necessary to remember that they, including the roentgen examination, are not without a considerable percentage of error, and that the basis of careful diagnosis must be common sense, good judgment, and a study of the individual. The history and clinical observations must remain paramount. The influencing factors of general systemic disease, the study of resistance to infection and the virulence of the micro-organisms must not be overlooked in evaluating the mystic maze of laboratory aids and technic. In the scientific fervor for chemical, cytologic and bacteriologic evidence one must not forget that the patient is not a guinea-pig but a member of the human family with an individuality.

Dr. I. S. Kahn, San Antonio, Texas: For about a year I have studied the nasal smears in every person with vasomotor rhinitis coming to my office for diagnosis or treatment, and also in borderline chronic cases referred to me by rhinologists for decision as to the existence of nasal allergy. Naturally, easily diagnosed cases of irritating lesions such as fissures, ulceration, foreign bodies, parasites or impingement, that might produce eosinophilia were not referred, and I have no records on such lesions, and there are none in the literature. In every case showing nasal smear eosinophilia that I have seen, a definite allergic hypersensitivity was ultimately determined to be the sole, or a complicating factor. This was found *unexpectedly in several* cases of so-called chronic sinusitis referred by rhinologic friends to be used as controls for this work. In *my experience to date, within the limitations* of the irritating conditions mentioned, every case of nasal eosinophilia above 3 per cent has meant allergy and has been proved either by significant positive skin tests or environmental study, when positive skin tests were not secured, a condition now recognized as not rare by practically all allergy workers. The cytology of infections in the known allergic cases included in this study has shown also that the changes in the allergic state may be considerably modified by infection, and when such infection has occurred in an allergic individual, as shown by a complicating polynuclear cytosis, or by a polynuclear cytosis replacing previous eosinophilia, attention to proper treatment has greatly improved the results of therapy based on allergy alone, a matter of decided importance. In my experience, the hay fever cases temporarily failing to show eosinophilia are at times the cases complicated by infection, cases of extreme severity in which the allergic diagnosis is unquestionable, but in which the discharge is purely watery and there are no cells, and cases seen in a state of temporary quiescence. A case of feather, house dust or pollen sensitivity, with definite nocturnal or early morning symptoms of considerable severity, may be totally quiescent allergically and symptom free by afternoon after several hours of freedom from antigen contact, and the true state of affairs missed by both the examiner and the laboratory. In those cases limited principally to nocturnal or early morning activity, the material can be collected on a roughened cellophane handkerchief in the home as, sealed in a jar, it will remain fit for examination for several hours. For the allergy worker these routine smear tests are of decided value in proving the existence of the condition of hypersensitivity when the initial routine diagnostic skin tests are negative, leading to further investigation either by further skin testing or environmental study, or, a matter of as great importance, to the detection of unsuspected complicating infections requiring additional appropriate treatment.

Dr. George Piness, Los Angeles: The discussion of Dr. Dean's paper leads one to believe that this work is new, but a similar study has been carried on in my laboratory for some fifteen years, and in discussion with Dr. Dean and others, eosinophils were suggested as being characteristic but not always pathognomonic of allergic disease. The eosinophil picture was *suggested as an aid in the differential diagnosis* of allergic and other otologic diseases. The laboratory observations should not be used alone for diagnostic purposes but merely to substantiate diagnosis made from the clinical history and physical signs. In a series of 159 children studied at the allergic clinic of the Children's Hospital of Los Angeles, routine nasal smears were made. Of this group, fourteen were diagnosed as nonallergic prior to the examination by the otologist. Nasal smears and washings in this group revealed eleven negative as to eosinophils and three positive, bringing out the fact that allergic disease is readily recognized and in the questionable cases eosinophil studies on nasal smears and washings are of great value.

Dr. L. W. Dean, St. Louis: In making cytologic examinations of nasal and ear discharges, sometimes the observations are not what are expected. For one year I have looked for an increase of eosinophils in ear discharges. In those cases that are definitely allergic, in which there is an abundance of eosinophils in the nasal discharge, the ear discharges have been disappointing so far as the eosinophils are concerned. Many cells have been found which stain with eosin, but they are not granular. They are not eosinophils. In connection with the use of tissue secured at operation in determining the micro-organisms present, as mentioned by Dr. Mosher, the material secured at the time of operation is macerated and used for making cultures. The viable organisms should be in the tissue even if absent from the pus. I appreciate Dr. Shurly's point that clinical judgment is what counts. That goes without saying. It will always be the most important thing. Regarding eosinophilia in the nasal discharge being pathognomonic for allergy, as suggested by Dr. Kahn, I will say that this is not in accordance with what I have found. It is not safe to make a diagnosis of allergy on the basis of an increase in eosinophils in the nasal discharge, nor does the absence of eosinophils exclude allergy. In a case of digitalis poisoning, an enormous number of eosinophils were found in the nasal discharge. When the digitalis was discontinued, the eosinophils disappeared. When it was again administered, they reappeared. In a case of carcinoma of the maxillary sinus no eosinophils were found the day following operation; the second day only a few were found but on the third day there were great clouds of them in the nasal discharge.

CONVULSIONS IN CHILDHOOD

STUDY OF FOUR HUNDRED AND NINETEEN CASES

M. G. PETERMAN, M.D.
MILWAUKEE

This study concerns the selected case records of 419 children under 15 years of age who were admitted to the Milwaukee Children's Hospital because of convulsions. The selection of private and charity cases is limited to include only those in whom every reasonable effort was made to establish a diagnosis (table 1). This series represents 1.9 per cent of the total admissions (22,036) to this hospital in the last nine years. The small number of cases (28) listed in the tables under "Cause unknown" represent patients in whom it was impossible to establish a diagnosis after utilizing all of the facilities available in our institution. While they are an admission of the limitations of our ability, they are included without hesitation as a realization of some of the unsolved problems in pediatric neurology.

A great deal of clinical study and careful animal experimentation have provided a certain understanding of the mechanism of the convulsive state. While the precipitating factors and the entire mechanism of a convulsion are not clear, there are certain features which are rather generally accepted. Most convulsions are *probably immediately due to a cerebral vasomotor* reaction which produces first cerebral anemia (tonic stage) followed immediately by a cerebral congestion and edema (clonic stage) (Foster Kennedy[1]). Compression of the carotids and vagi in human subjects has produced clonic spasms and loss of consciousness (Leonard Hill[2]). In experiments on cats, cutting off

From the Department of Pediatrics, Marquette University Medical School, and the Milwaukee Children's Hospital.

Read before the Section on Pediatrics at the Eighty-Third Annual Session of the American Medical Association, New Orleans, May 12, 1932.

[1] Kennedy, Foster: Epilepsy and the Convulsive State, Baltimore, Williams & Wilkins Company, 1931.

[2] Hill, Leonard: The Physiology and Pathology of the Cerebral Circulation, London, J. & A. Churchill, 1896.

the cerebral and medullary circulations was followed by unconsciousness, bladder and rectal evacuation, severe tonic convulsions and then flaccidity. A return of the circulation was followed by clonic convulsions (Pike and others[3]). "Convulsive attacks which follow temporary cerebral anemia can be regularly prevented by an artificially produced cerebral circulation of saline solution during the compression of the innominate and left subclavian arteries" (cats) (Elsberg and Stookey[4]).

The significance of cerebral edema in epilepsy has been known since the time of Hippocrates and has been more recently substantiated by the works of Alexander, Elsberg and Pike, Dandy, Mixter, Wartenberg, Carpenter, Fay and others.[5] The knowledge of this edema has been utilized in the treatment of epilepsy by dehydration (Dandy, Fay, McQuarrie and Peterman[6]). Possibly the effectiveness of the ketogenic diet is due to the dehydration it produces (Peterman[7]). It has long been known that the ketosis (Wilder[8]) is not the effective factor.[9] However, the peculiar susceptibility of the idiopathic epileptic patient to the periodic recurrence of his seizures, which are often of stereotyped character, has not been satisfactorily explained.

The high incidence of convulsions in childhood, particularly between the ages of 6 and 36 months, has been the subject of a great deal of speculation. There would be no particular advantage in reviewing the various theories that have been proposed to explain this frequency. Among them are the "incomplete development of the cortex," "incomplete myelinization of the nerves," "suppression of the cortical motor system" and many others.[10] With the present knowledge of the incidence and possibilities particularly of cerebral birth injury and hemorrhage, spasmophilia, epilepsy and acute infections, these theories are superfluous for all practical purposes. The infant and the child are subject to certain diseases, which in themselves are the exciting factors or indirect causes of convulsions. When the period of incidence of these diseases is passed, and thus the exciting causes are removed, the incidence of convulsions is greatly lowered. In most cases a thorough study will reveal the cause of the convulsion. Such a study also eliminates cutting of teeth, enlarged thymus, adhesions of the foreskin or clitoris and worms from the list of causes. There are no such diagnoses in this series.

It is our practice to obtain as complete a history as possible. Since in many cases of convulsions the physical findings after the attack may be entirely negative or normal, a great deal of emphasis must be laid on the history. The family history, if complete and reliable, will indicate whether or not a hereditary defect may be anticipated. The character of the pregnancy, the time of gestation and the type of labor will indicate whether the child has possibly had an intracranial injury. A description of the subsequent mental and physical development is of great value in determining the relationship of abnormal findings to the convulsions or vice versa. While the type and character of the convulsions may sometimes be observed, one is entirely dependent on the history for the frequency. About 75 per cent of our patients had convulsions in the hospital; thus in 25 per cent we were dependent on the history alone. The patients with idiopathic epilepsy have notoriously few seizures during a short period in the hospital (Peterman[11]).

Therefore, the convulsions are best classified according to age. Such a classification has been developed in this study and has proved to be of great clinical value (tables 2, 3, 4, 5 and 6). The small number of infants in the first month of life is characteristic of most children's hospitals.

The largest number of cases, 34.4 per cent, were diagnosed as idiopathic epilepsy. It is rather well known that most convulsions in children, particularly after 3 years, are due to epilepsy. However, this is no justification for the common error of making this diagnosis without further investigation. The diagnosis of idiopathic epilepsy is made by exclusion and only when all organic possibilities have been eliminated. In this paper the petit mal seizures are included as convulsions.

Twenty-one and four-tenths per cent of the convulsions were caused by acute infections. Under this heading are included the acute infections of the upper respiratory tract, otitis media, the onset of pneumonia and the onset of some infectious diseases.[12] The convulsion is probably the response of the organism to the invasion of the blood stream or meninges by the microorganisms (septicemia), or to the dysregulation of the water balance which many infections produce (cerebral edema).

Total	142	100.0

Spasmophilia caused the seizures in 16 per cent of the patients, and 76 per cent of these children were between 6 and 36 months of age. There were 9 infants between 2 and 6 months of age in whom the diagnosis of infantile tetany or spasmophilia was made. In 5 the blood serum calcium on admission was 7.9, 6.3, 7.5, 7.5 and 7 mg., respectively. In the remaining 4 the diagnosis was made on the basis of convulsions with carpopedal spasm, positive Chvostek and Trousseau signs and positive Erb electrical reactions. A discussion of tetany in young infants is not in order in this paper.

Thirteen and one-tenth per cent of the patients had convulsions on the basis of cerebral birth hemorrhage or injury or a residue of these lesions. A number of investigators have demonstrated that trauma can render an area of the brain unstable. Of 25,000 soldiers who suffered injury to the brain during the World War, in 4 per cent convulsions subsequently developed.[13] The studies of Sharpe and Maclaire, M. Hines Roberts, L. Howard Smith and others on the spinal fluid of new-born infants have demonstrated a probable injury in between 10 and 15 per cent of all infants.[14] The effect of this birth traumatization has been well presented in the classic works of Ehrenfest, Ford and others.[15] Whether the birth traumas produce immediate symptoms or not, they are capable of lowering the threshold of irritability (Timme)[16] or, by subsequent contraction of scar tissue (Foerster and Penfield),[17] of producing convulsions.

In 6.7 per cent of the patients the diagnosis could not be established.

The remaining 8.8 per cent constitute a miscellaneous group in which tetanus occurs the most frequently.[7]

CLASSIFICATION ACCORDING TO AGE

New-Born Infants (to 1 Month) (7 Cases).—While this series is small, the findings coincide essentially with those of larger groups in that cerebral birth trauma is a most common cause of convulsions.[18] The explanation was given previously. With a history of prematurity, prolonged or difficult labor or cyanosis at birth, a subsequent convulsion should immediately suggest the possibility of a birth injury. A spinal puncture is of the greatest value in diagnosis. If the delivery has been uneventful and a fever or other signs of infection precede the convulsion, another cause may be considered. A leukocyte count and possibly a blood culture will be of assistance in making the diagnosis.

Infants from 1 to 6 Months (54 Cases).—Contrary to many authors, convulsions are not infrequent in this period (12.9 per cent of this series). Here acute infections play the predominating rôle in the etiology (33.3 per cent of the cases). The cerebral birth injury residues are next in frequency (18.5 per cent). This age period contains the largest number of patients (11 per cent) with convulsions of unestablished origin.

Infants Between 6 and 36 Months.—This period has the highest incidence of convulsions (147 cases, or 35 per cent of the series. The acute infections, particularly the onset of the acute infectious diseases, are the most frequent cause of convulsions at this age (52 cases, or 35.3 per cent). These cases are recognized by the onset of convulsions with fever and leukocytosis. In this period spasmophilia or tetany constitutes an almost equal number (51 cases, or 34.7 per cent). These cases appear most commonly in the spring and fall as interrupted healing of rachitis (Gerstenberger and his associates[19]). They are usually diagnosed on the basis of characteristic convulsions preceded by irritability, facial twitching or laryngo-

spasm in infants with evidence of rachitis. The convulsions, which are characterized by carpopedal spasms, are usually precipitated by or associated with an acute infection of the upper respiratory tract. The diagnosis may be confirmed by the clinical findings of a Chvostek and a Birk (peroneal) nerve sign, the Trousseau phenomena and the Erb electrical reaction, by roentgenologic signs of a beginning healing of rachitis and by a usually low calcium and high phosphorus content of the serum. The cerebral birth injury residues constitute 11.5 per cent (17 cases) of this group and are usually characterized by a history of birth injury and a delayed development. Physical examination often reveals spasticity and increased and unequal reflexes. The convulsions may be precipitated by an acute infection. Ten cases, or 6.7 per cent, are due to idiopathic epilepsy. The high incidence of acute infections and spasmophilia in this period justifies the separation of this group from the following one.

After 3 years and through puberty, idiopathic epilepsy assumes the major rôle in the causation of convulsions, while cerebral birth injury residues take second place, and the acute infections rapidly decrease in number.

Between 3 and 10 Years.—This is the second largest group of cases (142 cases, or 34 per cent). Epilepsy is responsible for 81 cases, or 57 per cent. These patients present a family history of epilepsy or hereditary nervous disease in over 50 per cent of the cases, while the past history is usually irrelevant. The convulsions recur more or less periodically, with aurae in about 50 per cent. There is often a history of dietary indiscretion and constipation immediately preceding the attacks. The physical findings and laboratory examinations between attacks are usually negative (Peterman [20]).

The cerebral birth injury residues comprise 13.4 per cent of this group of cases (19 cases) and are characterized by the findings given previously.

The acute infections constitute 15 cases, or 10.6 per cent.

Between 10 and 15 Years.—This group of 69 children (6.4 per cent of the series) differs from the preceding one in the lower incidence of cerebral birth injury residues (6 cases, or 8.8 per cent) and acute infections (2 cases, or 2.9 per cent). Idiopathic epilepsy is responsible for 50 cases (72.5 per cent).

Most of the miscellaneous diagnoses (37 cases, or 8.8 per cent) are self-explanatory. The 6 cases of gastro-enteritis include a group of children with a history of dietary error followed by vomiting and diarrhea and convulsions in whom the physical findings were otherwise negative. The 3 cases of congenital cerebral defect were ones of porencephalia, which was confirmed by encephalograms. There were 2 cases of polioencephalitis which conform to Strümpell's and Marie's original descriptions of this condition.[21]

There is a strikingly low incidence of syphilis, hydrocephalus and injury (traumatic) to the skull in this series.

Routine examinations of the stools for intestinal parasites have given negative results in this series, and intestinal parasites are eliminated as a cause.

Examinations of the blood have revealed leukocytosis (over 10,000) at the time of entrance in 168 cases. Of these, 42 were cases of spasmophilia, 41 of idiopathic epilepsy, 36 of "acute infections," 18 of cerebral birth injury residue and the remainder of miscellaneous conditions. Forty-eight of these 168 patients with leukocytosis had a polymorphonuclear count over 70 per cent. The counts were found in 18 cases of epilepsy, 10 of "acute infections," 5 of "unknown cause," 4 of meningitis and the remainder in miscellaneous conditions.

The spinal fluids were abnormal or pathologic in 22 cases. (The cell count was over 10 in 7 cases of "acute infections," in 5 of meningitis, in 4 of epilepsy, in 3 of cerebral birth injury residues and in 2 of tetanus, and there was a positive Wassermann reaction in 1 case of congenital syphilis.)

There were 4 deaths in convulsions, 3 in tetanus and 1 in acute infection (bronchopneumonia).

IMMEDIATE TREATMENT

The simplest, quickest and most effective treatment of a seizure is the administration of chloroform by inhalation.

The most logical treatment, which is equally simple and effective but acts more slowly, is the administration of hypertonic solutions of magnesium sulphate (50 per cent), dextrose (or cane sugar) (from 25 to 50 per cent) or sodium chloride (from 5 to 10 per cent) by mouth or rectum (from 2 to 8 ounces [59.2 to 236 cc.]). The solutions may be given from every four to six hours as indicated. Sterile solutions of magnesium sulphate (25 per cent) may be injected intramuscularly (from 5 to 10 cc.) or intravenously (from 2 to 5 cc. of from 10 to 20 per cent, slowly) for rapid effect.

The spinal fluid should be drained for examination and for the relief of pressure (except in cases of suspected tumor of the brain). In intracranial hemorrhage lumbar drainage removes the blood, irrigates the subarachnoid space and tends to prevent blood clots and the collection of fluid. It should be preceded by the intramuscular injection of blood. Spasmophilia or tetany may be treated immediately by the intravenous or intramuscular injection of calcium preparations (calcium gluconate) followed by viosterol in large doses.

Sodium barbital may be injected intramuscularly or subcutaneously in doses of from ¼ to 1½ grains (0.016 to 0.097 Gm.).

Between seizures phenobarbital may be given by mouth to prevent a second seizure (from ¼ to 1½ grains).

The treatment of recurring convulsions is a large subject in itself and depends on the basic cause.

COMMENT

Four hundred and nineteen cases of convulsions in children have been studied, and a diagnosis has been established in 93.3 per cent. The study includes a complete history, a careful physical examination, including neurologic studies, a blood count, a Wassermann test of the blood and microprecipitation tests, urinalysis, examination of the spinal fluid (except in spasmophilia), examination of the fundi, x-rays of the skull and examinations of the stools. In the past three years encephalograms have been made in doubtful cases.

The findings reveal that certain diseases peculiar to childhood are the direct causes of most of the convulsions. While some children may be said to be particularly susceptible to the convulsive state, this study indicates that there is usually a physical basis for this susceptibility (spasmophilia or epilepsy) which is amenable to treatment.

[20] Peterman, M. G.: Wisconsin M. J. **31**: 169 (March) 1932.

[21] Strümpell: Jahrb. f. Kinderh. **22**: 173, 1885. Marie, P., and Foix, C.: Triplégie spasmodique sclérose intracérébrale, Rev. neurol. **25**: 346, 1913.

Every convulsion produces a certain amount of cerebral injury and therefore lowers the threshold for subsequent seizures. Every convulsion demands a careful study and effort to prevent a recurrence. It is extremely unfortunate that there are still physicians who consider convulsions a necessary evil of childhood and advise parents that the child will "outgrow" the tendency.

While many patients came in with diagnoses of thymic convulsions, worms, teething convulsions or toxic convulsions, a thorough examination eliminated these diagnoses. These conditions must truly be exceedingly rare. The teething convulsions were usually spasmophilias.

During the past year I have made moving pictures of the various types of convulsions in order to study the convulsive stage in detail. No conclusions have been drawn, but it appears that the idiopathic epilepsies represent stereotyped reactions which are also observed in some brain injury residues (birth and traumatic), while most of the remaining seizures represent incoordinated "explosions."

CONCLUSIONS

A practical classification of convulsions in childhood is presented. Most of the convulsions in new-born infants are due to acute infections or to cerebral birth injury; in later infancy, they are due to spasmophilia, and in childhood, to idiopathic epilepsy. A basic cause may be found in most cases. Convulsions are just as serious a symptom in children as they are in adults. There is no justification whatever in minimizing the symptom because of the age or in informing parents that time will remove the cause.

ABSTRACT OF DISCUSSION

Dr. Harry Lowenburg, Philadelphia: Some years ago, before this section, I believe, Drs. Powers and Park, at that time at Yale, did some studies in the treatment of convulsions in whooping cough. They came to the conclusion that many of these children who develop convulsions during whooping cough, and also many children who initiate their acute infectious diseases with convulsions, were essentially spasmophilic. They made calcium studies and were able to demonstrate this in a large number of cases. The conclusion which they drew was that it would be possible, as a prophylaxis in the treatment of whooping cough and of other conditions wherein convulsions might be expected, to regard these children as spasmophilic and treat them accordingly with injections of calcium and with the hormone of the parathyroid. I followed this teaching for many years and, I think, to great advantage. Dr. Peterman did not mention in his paper the use of calcium, and of parathyroid extract. Perhaps it was broadly covered under the direction to treat the basic disease. If cerebral edema is a cause for convulsions in these children, it seems quite in order to make use of calcium and of the parathyroid hormone.

Dr. M. G. Peterman, Milwaukee: I have had only two children with pertussis develop convulsions. Neither of them had a low blood calcium. One had a blood-tinged spinal fluid; the other had fluid under increased pressure. But neither presented what was considered as spasmophilia. Therefore, I have not included that point in the discussion. The series shows that the convulsions in infants are due to cerebral birth injuries or acute infections; in later infancy, to spasmophilia; in childhood, to idiopathic epilepsy. I believe that convulsions are just as serious a symptom in children as they are in adults and that there is no justification whatever in minimizing the symptoms because of the age, or in informing parents that time will remove the cause.

THE MORTALITY FROM ABSCESS OF THE BRAIN

FRANCIS C. GRANT, M.D.
PHILADELPHIA

Of all the lesions involving the brain, none requires more judgment and experience in its successful management than an abscess. That an abscess exists may be difficult of proof. Frequently when its presence seems unquestioned, a precise localization cannot be made. Lastly, when the diagnosis of an abscess in a definite area is reached, the decision as to the proper time and method for its evacuation taxes all the surgeon's skill. All too often diagnosis and localization are proved correct, but the patient dies as the result of imperfectly applied surgical measures.

This report is based on a series of fifty-one verified abscesses of the brain, thirty-nine from the neurosurgical service of the University Hospital, eight from the Graduate Hospital and four from Mount Sinai Hospital. The etiology and pathology of brain abscess have been extensively reviewed by many writers. Further repetition of these points seems unnecessary. I wished to determine from an analysis of these fifty-one cases whether the high mortality accompanying abscess of the brain is due to errors in diagnosis and localization, or whether the time in the development of the abscess at which drainage is instituted and the means employed in drainage are the cause.

Table 1.—*Fifty-One Cases of Brain Abscess*

Preoperative localization and diagnosis correct.....	39 or 76.4 per cent
Cases diagnosed as tumor but localization correct...	4
Total localization correct........................	43 or 84.3 per cent
Errors in localization and diagnosis cannot account for mortality	

Among the fifty-one verified cases, a preoperative diagnosis of abscess was made in thirty-nine. In four the lesion was considered to be a tumor rather than an abscess. All these forty-three patients were operated on and the abscesses drained. One child was admitted unconscious with signs of increased intracranial pressure. The history obtained was inadequate. As the situation was desperate and no positive diagnosis could be reached, ventricular tap was immediately performed for relief of pressure in the hope that the child could be kept alive until a more thorough examination was made. However, she died six hours later. Autopsy showed a cerebellar abscess. In four cases, abscess was suspected, and drainage attempted unsuccessfully. But since in each instance the localization was incorrect, the abscess was subsequently found at autopsy. In two cases a diagnosis of meningitis was made on admission and no operation seemed indicated. Autopsies showed a subcortical abscess of the frontal lobe, ruptured into the anterior horn of the ventricle, and a subdural frontal abscess with generalized meningitis. Another patient was awaiting operation for cerebellar abscess, but died suddenly from a cerebellar crisis. Autopsy verified the localization of the abscess.

These figures seem to show clearly that diagnosis and correct localization of the brain abscess were possible in roughly 80 per cent of this series. Errors in deter-

---

From the Neuro-Surgical Clinics of the University Hospital and the Graduate Hospital of the University of Pennsylvania, and the Mount Sinai Hospital.

Read before the Section on Nervous and Mental Diseases at the Eighty-Third Annual Session of the American Medical Association, New Orleans, May 13, 1932.

mining the presence and situation of a brain abscess do not, therefore, seem to play an important part in accounting for the high mortality rate.

Presuming that the diagnosis of brain abscess is made and a decision reached as to its position, at what period in its development should drainage be attempted? Should evacuation of the abscess be carried out promptly, or should intervention be delayed until the defensive mechanism of the brain has had ample time to wall off and encapsulate the infection? If accepted methods of treating infection elsewhere can be applied to intracranial suppuration, then surgical intervention should be postponed until localization has occurred. No experienced surgeon would consider incising and draining an abscess in any other area of the body before encapsulation was completed. Furthermore, the brain is less well organized than other regions to combat suppuration. The glial elements of the brain are highly specialized cells, well equipped to carry out their proper function, but they react slowly in localizing infection. Moreover, the brain is relatively poorly supplied with fibrous tissue, which is the foundation of any "walling off" process. Therefore, since delay in establishing drainage until localization of the infectious process has occurred is a major surgical principle, it should be strictly adhered to in dealing with brain abscess. But a longer period must be allowed the brain to complete the encapsulation, lest drainage be inserted before the defensive mechanism has functioned properly.

The development of an abscess of the brain parallels closely that of an abscess elsewhere in the body. Infection is implanted, adjacent cells die, and leukocytes surround and invade the infected area. "Cerebritis," local tissue necrosis without definite pus formation, occurs. Liquefaction of the center of the infected area follows. Finally, encapsulation may take place, unless the virulence of the organism is such that the defensive mechanism of the brain is overwhelmed. Obviously drainage during the stage of "cerebritis" is useless, for the infected area contains little or no free pus that can be evacuated. Even after the fluid pus has formed, drainage is of questionable propriety unless encapsulation has occurred. Encapsulation is evidence that the defensive reaction of the brain tissue has been able to control and localize the infection. Whenever possible drainage should be delayed until the abscess is circumscribed. The defensive mechanisms of the brain are thereby given sufficient time to complete encapsulation without the added handicap of operative trauma. Furthermore, isolation of the infecting organisms tends to decrease their virulence. Lastly, the adjacent tissues become sensitized to the infecting organism so that when drainage is instituted spread of infection about the drainage tract is less likely to result.

The results in this series of cases indicate the dangers of operation on an abscess of the brain before encapsulation has occurred. Nineteen such cases were verified by operation or at autopsy. In fourteen cases the abscesses were drained; four in the "cerebritis" stage, so that little or no pus was obtained. Three patients were not operated on because a diffuse meningitis was present when they were first observed. In two cases evacuation was attempted, but the localization was faulty, and the position of the lesion was discovered only at autopsy. Lack of encapsulation of the infection was demonstrated at necropsy in twelve cases. The operative notes in seven other cases state that no resistance suggesting capsule formation was met by the exploring cannula just prior to the appearance of pus in its lumen. None of these nineteen patients survived, although drainage by precisely similar methods was followed by recovery in instances in which definite encapsulation was encountered. While it is admitted that a sense of resistance to the tip of the exploring cannula may not be an accurate means of determining capsule formation, nevertheless, it seems sufficiently accurate to sustain our position. In three cases in which the operative notes stated that a capsule was present because of resistance to the cannula, microscopic examination later showed that no true encapsulation had occurred. However, the converse is not true. In no instance in which the operator held the opinion that the infection was not walled off was a capsule demonstrable at autopsy.

Based on this record, it is the opinion of my associates and myself that surgical intervention for evacuation of a brain abscess should be deferred until encapsulation seems assured. We do not believe that an unlocalized area of "cerebritis" should be classed as an abscess of the brain any more than a spreading infection elsewhere in the body can rightfully be designated as an abscess. Furthermore, we are doubtful as to the propriety of surgical intervention in these early cases. If any surgical measure is undertaken the method used should be most conservative. When the exploring cannula fails to evacuate pus or if pus is found without a change in resistance suggesting the presence of a capsule, the operator should think carefully before he inserts permanent drainage. The trauma resulting from introducing a drain at this time may seriously handicap the defensive reaction of the brain. A simple tap and evacuation of pus will relieve existing pressure symptoms. A second evacuation with drainage can be done at a later date when encapsulation of the abscess has been more completely established.

Table 2.—*Time of Encapsulation*

Operated on within 2 weeks	13
10 unencapsulated	
3 encapsulated	
Operated on third to fourth week	18
8 unencapsulated	
10 encapsulated	
Operated on fifth to sixth week	5
2 unencapsulated	
3 encapsulated	
All operated on after sixth week found encapsulated	

Granting that sufficient time should be permitted a brain abscess to encapsulate, are there definite signs which indicate with certainty that this has occurred? How long should drainage be delayed to permit complete encapsulation? Thirteen abscesses were verified in the first two weeks. Ten were unencapsulated; seven were proved at autopsy and three by operation. The four cases in which drainage was instituted during the period of "cerebritis" fall in this group. Twelve abscesses were subcortical. One of the three encapsulated abscesses was extradural following frontal osteomyelitis. In eighteen cases drainage was performed during the third and fourth weeks. Eight abscesses were recorded as unencapsulated, of which four were verified at autopsy. Five patients were operated on in the fifth or sixth week. Three of the abscesses were reported as encapsulated and two as unencapsulated, all on operative evidence alone. Each of the fifteen abscesses in the patients in this series operated on after the sixth week following the onset of symptoms appeared to have a definite capsule. It would seem, then, based on the criteria for encapsulation herein adopted, that thorough walling off of a subcortical area of infection within the brain requires about four weeks from the onset of symptoms, provided that the defensive mechanism of the brain is not overwhelmed from the start by the virulence of the infection.

Is there any other means by which encapsulation may be determined? Based on the records of these cases, the neurologic findings were not of much aid from this point of view. In only three of the nineteen cases of unencapsulated abscesses was there observed a definite increase in the neurologic signs suggesting a spreading lesion. In the other cases a group of symptoms appeared, at times slowly and in other instances abruptly, but all were apparent in some degree from the onset. These early manifestations often increased in severity, but except for evidence of increased intracranial pressure, such as headache, increasing stupor and slow pulse and respiration, it is curious how rarely a fresh neurologic symptom suggesting a spread of infection from one area into an adjacent part of the brain became conspicuous in the clinical picture. Lumbar puncture was performed so infrequently that no real information can be gleaned from this source. Fundiscopic examinations were made in forty-eight cases. Of eighteen unencapsulated abscesses, there was no choking in eleven; the disks were blurred in two, and actual choking varying up to 4 diopters in each eye occurred in five. Of the thirty-two encapsulated abscesses, there was no choking in six; blurring of the disks occurred in four, and in twenty choking of various degrees up to 7 diopters was noted. No record of the condition of the eyegrounds could be found in three instances. In two of the six encapsulated cases without choking, the abscess had probably been present for at least a year, so that possibly the swelling had been present and subsided. In these two instances the abscess followed a trauma and the inclusion of a foreign body within the brain. It seems, therefore, that the presence of choked disk suggests that encapsulation has probably occurred. We have not sufficient information as to the stage of the papilledema to bear out Lillie's[1] contention that surgical intervention is most successful when it is withheld until no further increase in the choking is to be noted.

Table 3.—*Operative Results*

19 cases unencapsulated abscess, mortality	100.0%
30 cases encapsulated abscess, 20 lived, 10 died, mortality	33.3%
Time of operation definitely affects results	

Table 4.—*Results of Fundiscopic Examination*

18 Unencapsulated Abscesses	
No choked disk	11
Blurred disk	2
Choked disk up to 5 diopters	5
30 Encapsulated Abscesses	
No choked disk	6
In 2 of these abscess present for at least a year and choking may have subsided	
Blurring of disk	4
Choked disk up to 7 diopters	20

The failure to save a single patient with an unencapsulated abscess of the brain by operative measures can lead to only one of two conclusions; either the surgical measures were ill timed or they were ineffectively applied. Drainage should certainly have been delayed in the four cases in which it was inserted during the stage of "cerebritis," for little or no pus could be evacuated. In two of these cases the "cerebritis" followed trauma. Three other patients were proved to have multiple abscesses, frontal and occipital, parietal and cerebellar and extradural and intradural frontal, obviously hopeless conditions. It should be stated, however, that in none of these instances was the presence of the second abscess suspected until revealed at autopsy. Since precisely similar methods of drainage were employed in all abscesses whether found to be walled off or not, a comparison of the results obtained by operation on the encapsulated group may serve to show whether faulty surgical technic was the cause for the overwhelming mortality when operation was carried through before localization was complete.

Thirty-two encapsulated abscesses round out this series. One patient died in the ward while awaiting operation. Another was refused operation owing to the abrupt development of frank meningitis. This case is classified as an error in diagnosis, since the presence of an abscess was entirely unsuspected. Autopsy revealed a well encapsulated subdural collection which had ruptured into the subarachnoid space. Earlier surgical intervention might well have resulted in recovery. Thirty patients with encapsulated abscesses were operated on and the abscesses drained with twenty recoveries and ten deaths. In three such cases the abscesses were drained in the second and third weeks following the onset of symptoms; one patient recovered and two died. One death occurred from sudden compression following apparently perfect drainage of a cerebellar abscess. Autopsy showed the tube within the abscess; the abscess was entirely collapsed, but the cerebellar lobe was swollen from traumatic edema. A pressure cone was demonstrable about the medulla, and the cerebellar tonsils were jammed in the foramen magnum. A subtemporal decompression or a ventricular tap might have saved this patient. He was found dead in bed the fourth night following operation. The pulse and respiratory rate gave no indication of increased pressure. As he had had essential epilepsy for ten years, it was suspected that a convulsion might have occurred, raised the intracranial pressure suddenly and caused fatal medullary compression. The second patient was suspected of having an abscess, but two exploratory taps were negative. The diagnosis of tumor was therefore made, and an osteoplastic flap reflected. A large abscess was discovered and an attempt made to marsupialize the abscess by sewing the dura to the capsule, thus walling off the subarachnoid space. The bone flap over the cavity was removed. The abscess slowly extruded, and for a time the situation appeared favorable. However, the "cerebritis" spread slowly, and meningitis resulting in death appeared seven weeks later.

Table 5.—*Time of Drainage of Encapsulated Abscesses; Series of Thirty-Two Cases; Thirty Operated On*

	Cases	Recovered	Died
Second to third week	3	1	2
Fourth week	11	8	3
Sixth week	4	4	0
Eighth week	4	1	3
Thirtieth to fiftieth week	5	3	2
One year	3	3	0

---

[1] Lillie, W. I.: Surg., Gynec. & Obst. 47:405 (Sept.) 1928.

Eleven encapsulated abscesses were drained in the fourth week of symptoms. Eight patients recovered and three died. One fatality resulted in a patient with multiple cerebellar abscesses only one of which was drained. The presence of two lesions was confirmed at autopsy. Both seemed of equal age and were not connected, so that it appears certain that the second abscess did not result from imperfect drainage or spread from the other. A second death followed the development of an internal hydrocephalus which resulted from imperfect drainage of a cerebellar collection. The third death in this group followed a simple tap and tap with insertion of drainage into a small deep-seated and toughly encapsulated abscess of the frontal lobe. The pus was located and evacuated at the first operation. Owing to the thickness of the capsule, it seemed doubtful whether drainage could be inserted. Two days later, the attempt was made, but the tube was implanted only with difficulty. Fatal meningitis developed a week later. Autopsy was refused. It is my impression that we should have been satisfied with a simple tap and not traumatized the tissues by the insertion of drainage.

Four patients with localized abscesses were operated on during the sixth week of their formation. All of the patients recovered. Curiously enough, in this group are included two cerebellar abscesses that were simply evacuated and not drained. In one instance it was believed that a tumor of the vermis was present. Both patients are alive and entirely well four and two years later.

Four patients make up the group operated on two months after the onset of symptoms. Three died and one recovered. One fatality followed operation on the mistaken diagnosis that a tumor was present. A large, right frontal abscess was discovered. The bone flap was removed and the arachnoid space excluded by suturing the dura to the abscess wall. The faulty diagnosis spoiled an excellent opportunity for recovery, as fatality from meningitis promptly resulted. A second patient had an ipsolateral cerebellar and parietal lobe abscess and a sinus thrombosis. Only the cerebellar abscess was diagnosed and drained. Death resulted from rupture of the cerebral collection into the ventricle. The third patient obviously had an abscess of the right temporal lobe following infection beneath the temporal muscle involving the zygoma. When first seen only a blurring of the disk was noted. Operation was delayed to allow for more complete encapsulation. Sudden stupor developed five days later. An abscess containing about 50 cc. of colon pus was hastily evacuated. The patient never recovered consciousness and died five hours later. Our judgment was unquestionably at fault in this instance.

Five abscesses were drained from six to twelve months after the first appearance of the symptoms. Two patients died. One death occurred in an old depressed fracture with an encapsulated sequestrum. A small cerebral fungus was present before operation. A collection immediately beneath the fungus and surrounding the sequestrum was evacuated. A sudden medullary collapse occurred four hours later. Further exploration revealed a larger abscess more deeply situated below the cortex. This was promptly drained, but nevertheless, the patient died. The second death followed drainage of a right temporosphenoidal abscess in one stage through an opening in the bone 4 cm. across. The abscess was easily tapped and drainage inserted without difficulty, but a cerebral fungus resulted, followed in several weeks by meningitis.

Three chronic abscesses, which from the history were apparently present for at least a year, were drained. All of the patients recovered uneventfully. These thirty cases represent the results of surgical drainage in true brain abscess. All of the lesions had progressed beyond the stage of "cerebritis"; localization had occurred, and the defensive mechanism of the brain had the situation well in hand when drainage was instituted. That precisely similar methods of treatment prior to encapsulation resulted in such a strikingly different mortality rate emphasizes the importance of selecting the proper time in the development of the abscess for the insertion of drainage.

METHOD OF DRAINAGE

In the drainage of these abscesses, three principles have rigidly been followed. First, with the exception of the four cases in which tumor was suspected and a large flap turned down, the lesion was approached through a small opening in the bone. In almost every instance a trephine was made, never more than 2 cm. in diameter. Every effort was used to place the opening in the bone in that area beneath which the abscess most closely approximated the surface of the brain. No particular effort was made to drain through the point at which the infection crossed the meninges into the brain. Second, in twenty-two of the thirty encapsulated abscesses, the evacuation was carried through in two stages, the trephine opening being made, the dura opened and packing introduced in the wound for from twenty-four to forty-eight hours to produce meningocortical adhesions and to wall off the subarachnoid space. Fifteen of these patients recovered and seven died. Third, the drainage material used in all instances was a soft rubber tube. Except in four cases in which the patients were operated on under the

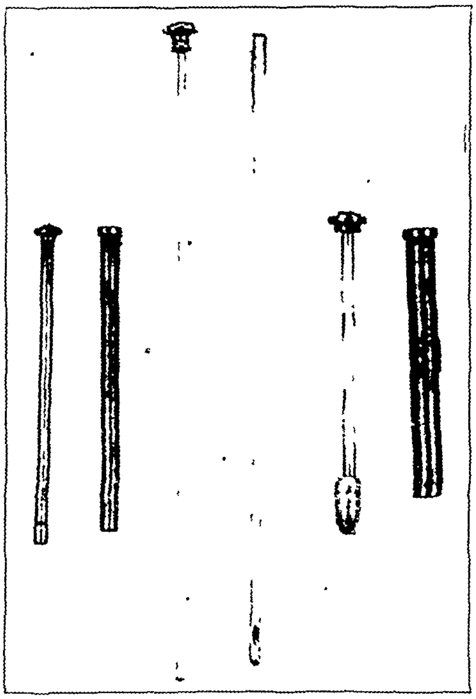

Fig 1 —Brain abscess cannulas. Exploring cannula and stylet (center). Two sizes of carriers and silver tubes to pass over the cannula into the abscess (right and left).

impression that the lesion was a tumor, the abscess cavity was never widely opened for inspection. Two of these patients, as has been stated, were treated by marsupialization of the abscess cavity. The after-treatment was modeled closely on King's[2] method; both patients died. In the other two cases, in which an osteoplastic flap was reflected, the abscess was opened, the pus sucked out, the cavity washed out with a mild antiseptic and the wound closed without drainage. One patient has had no symptoms suggesting a recurrence in the past four years, the other in the past eight months. In four cases, the abscess was tapped, but following Dandy's[3] suggestion no drainage was introduced. Three patients recovered and one died. All three patients have been symptom-free for over two years. Gauze packs have never been used in any of these cases to keep the cavity open or to act as drains, nor has the Moser drain, so strongly recommended by Cahill,[4] been employed.

One of the difficulties frequently encountered in attacking an abscess is the introduction of the drain. Considerable trauma may result to surrounding tissue with consequent spread of infection in an attempt to place the tube accurately in the abscess cavity. In an effort to solve this problem, we have made an exploring cannula of the usual diameter, but of double length. Over this cannula fits a sleeve with its lower end conical and tapering off to the exact size of the cannula (fig. 1). This sleeve carries snugly fitting silver tubes of various diameters. Once the exploring cannula is in the abscess cavity, the sleeve and tube are passed down the shaft to the point where the fingers steadying the cannula in the abscess cavity rest against the edge of the trephine opening. The reason for the extra length of the exploring cannula now becomes apparent, for its upper end projects out beyond the top of the sleeve. The operator's grip is next shifted on the cannula from below to above the sleeve, and he steadies the cannula by its upper end, as the sleeve passes down it into the abscess cavity. If the cannula cannot be steadied by its upper end and prevented from passing downward into the brain while the sleeve is being advanced into the abscess, there is great danger that both cannula and sleeve might progress together, and the tip of the cannula be plunged through the inner wall of the abscess. Once the sleeve and tube are in place, the cannula and sleeve are withdrawn, leaving the silver tube in the abscess cavity as shown by the escape of pus through its lumen. A soft rubber drainage tube is now passed down through the silver tube into the abscess and the tube withdrawn. By the use of this instrument we have been able to place a drainage tube accurately in any abscess cavity no matter how deeply seated, with a minimum of trauma.

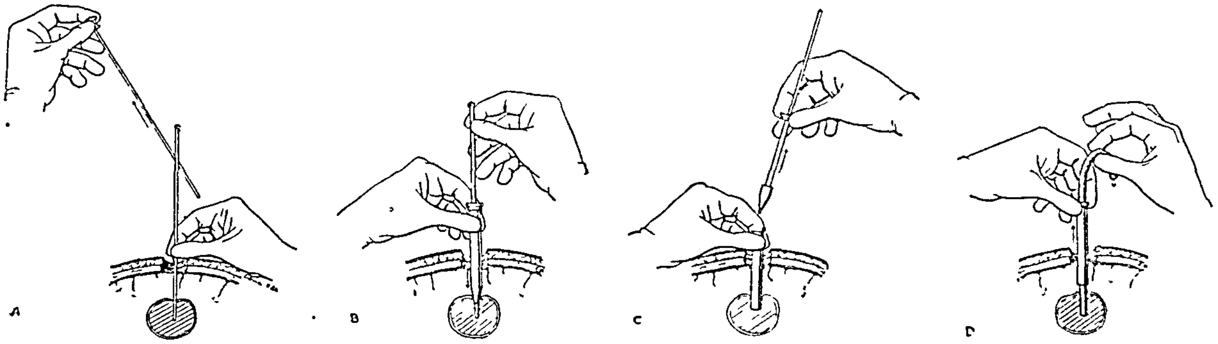

Fig 2—Diagram to illustrate the method of using the brain cannula *A*, the cannula is in the abscess, with the stylet withdrawn. *B*, sleeve and tube passing down the cannula into the abscess The cannula is made long so that its upper end may be grasped above the descending sleeve, thus securing the cannula and preventing it from passing down into the abscess with the sleeve In this way puncture of the inner wall of the abscess is prevented *C*, cannula and carrier withdrawn, leaving the silver tube in the abscess cavity. *D*, rubber drainage tube introduced accurately into abscess cavity through the silver tube. *The silver tube is then withdrawn, the rubber tube being left in place.*

COMMENT

It would appear from an analysis of the series of cases studied that the diagnosis and localization of brain abscess are no more difficult than for any other intracranial lesion. Ventriculography was used only four times as an aid in determining the situation of the lesion. In a fifth case, the abscess was encountered when an attempt was made to reach the lateral ventricle.

Drainage of a brain abscess before encapsulation has occurred has been uniformly disastrous in our experience. We admit that but one method has been employed. Possibly King's[2] technic, or the use of the Moser drain, might have given better results. Furthermore, we confess that we cannot describe any clinical symptoms that indicate with certainty that the infection is definitely localized. The figures presented seem to suggest that operation is most successful after the fourth or sixth week following the onset of definite symptoms. We are in entire agreement with the statement of McKenzie[5] that most cases in which an abscess of the brain is suspected are not surgical emergencies. Time should always be taken for careful study and complete examination so that localization is as accurate as possible. The high percentage of correct diagnosis in this series is due to a policy of delay until all studies are completed. If increased pressure was present, hypertonic solutions by vein were used to combat it. If the situation grew too acute, a trephine opening was placed over the area most strongly suspected, so that an emergency tap could be made promptly if necessary. Only two patients died because operation was delayed too long. Fourteen died because operation was performed too soon.

In the treatment of brain abscess, the surgeon is on the horns of a dilemma. Determination of the proper moment to drain an abscess is a critical point in successful treatment. If he operates too promptly, he may spread infection rather than evacuate it. If he delays too long, the abscess may rupture into the ventricle or subarachnoid space with disastrous results.

[5] McKenzie, K. G: The Treatment of Abscess of the Brain, Arch. Surg **18**: 1594 (April) 1929.

We feel strongly that delay is preferable to fumbling haste and imperfect localization. Delay permits the brain to wall off the infection, to build up resistance to the particular organism and, by encapsulation, to reduce its virulence. That three of four patients with well encapsulated abscesses recovered following simple tap and evacuation of pus from the cavity shows that in time these abscesses become sterile or the virulence of the infecting organisms becomes so attenuated that the defense mechanism of the brain can handle the situation, provided we do not handicap it by too much traumatism of the adjacent areas. A more accurate localization enables the surgeon to place the trephine opening in the skull in the best possible position to obtain free drainage.

Only one method of drainage has been used in this series, the insertion of a small rubber tube. This technic has been used because thereby a minimum of trauma to adjacent tissue results. We feel that our mortality has resulted for the most part from a spread of the "cerebritis" about the abscess due to ill timed drainage or too much trauma resulting from bungling attempts to insert a drain. Frank meningitis has been a terminal event in only a little less than half the cases. In a third of those in which meningitis developed the infection appeared over a week after drainage was instituted, suggesting a gradual spread of "cerebritis" into the subarachnoid space rather than its development as a direct result of the original operation.

CONCLUSION

An attempt has been made to determine the influence on the mortality from brain abscess of the following factors: difficulty in diagnosis and localization, time of treatment and method of treatment.

Our conclusions are as follows:

1. Brain abscess is not more difficult to diagnose and localize than any other intracranial lesion, provided sufficient care is taken in the study of the case.
2. A brain abscess should not be drained until it seems certain that encapsulation has occurred, preferably in the sixth week after the onset of symptoms.
3. Drainage by a small rubber tube has given satisfactory results. No matter what method is used, unnecessary trauma to surrounding tissue is to be scrupulously avoided.

ABSTRACT OF DISCUSSION

Dr. Ernest Sachs, St. Louis: I think everybody is agreed that the principle Dr. Grant laid down, that one should not operate on an abscess until it is chronic, is sound if one can wait that long. But it has been my experience, unfortunately, that one sees cases in which it is impossible to wait until one thinks a capsule is formed. Just how long it takes for a capsule to form, I don't know; certainly based on other pathologic evidence, a number of weeks. There is one point in Dr. Grant's paper that strikes one forcibly, and that is that in all the cases, whether encapsulated or unencapsulated, the treatment was the same. I should like to raise the point whether some of the patients in this distressing group of cases in which the abscess is apparently probably not yet encapsulated might not be saved if a different method of treatment was used than is used in the encapsulated abscess. A recent case has brought this home. Sudden unconsciousness necessitated action and a brain abscess was aspirated without draining. The patient made a complete recovery. I believe the procedure plays an important rôle, and what I am doing now in the chronic abscesses (and of course I always wait if I possibly can) is to aspirate the abscess repeatedly, if necessary, and not drain at all. I hope that this method of procedure will perhaps enable me to save some of these patients with unencapsulated abscesses. A condition that is not so very different, I think, might be cited. Thoracic surgeons are strongly opposed to opening a chest that contains fluid unless there is frank pus, but a stage is reached frequently in which the chest is so full of fluid that in order to relieve the pressure symptoms they have to evacuate the fluid, but they don't drain. If they drain too soon, they are likely to get a fatality. That condition might be compared to this condition of an acute abscess in which one can't afford to wait. I quite agree with Dr. Grant that one should wait if possible until the abscess is encapsulated. Even then, I believe, unless the capsule is right near the surface, it perhaps is wiser to aspirate and not drain. In two cases I have used King's method of marsupializing the abscess when the abscess was near the surface of the cortex, and both of the patients got well, but I think that was due to the localization of the abscess near the surface, so that meningitis did not occur and pus did not get into the subarachnoid space. There is one other point on which I don't quite agree with Dr. Grant: in my experience the diagnosis of brain abscess is often vastly more difficult than the diagnosis of a tumor. I have seen a number of cases of brain abscess in which I not only could not make a localization but I was unable to tell whether there was an abscess.

Dr. R. E. Semmes, Memphis, Tenn.: In regard to the question of whether encapsulation has taken place, in my experience the general signs of sepsis have been a good index and I have waited until the temperature became normal and until the leukocyte count dropped to normal. I also think with Dr. Sachs that when the abscess has been located with a ventricular needle the nature of the pus should determine what is done. I have followed the plan of tapping the abscess and having a smear made immediately at the table. If the abscess is encapsulated and the pus is sterile, no drain is inserted, the abscess simply being drained by tapping, and retapping if necessary. If organisms are demonstrated by smear, I put in a small tube drain; but I think that if through accident or necessity one has to tap an abscess before encapsulation has taken place, in these cases one should not insert a tube. It will be time enough later after repeated tappings, if it becomes necessary on account of refilling, to insert a drain. The next most important thing in determining mortality, I think, is the situation of the abscess. Perhaps I have had bad luck with cerebellar abscesses, but in my experience they have been much more apt to be fatal regardless of encapsulation or even what is found in the pus. I believe one should not put a drain in a cerebral abscess. In the small subtemporal space, edema following trauma and secondary encephalitis is so dangerous that tapping alone should be employed. I think that in the average case of brain abscess, especially when encapsulation has taken place and when few or no organisms are found, the continued trauma accompanying a foreign body, such as a tube in the brain, is more harmful than helpful.

Dr. Francis C. Grant, Philadelphia: Dr. Sachs and I are in accord except possibly in minor details. Given a patient, such as he described, who has had mastoiditis for a considerable time, with headache, and the sudden appearance of increased intracranial pressure, there is no question as to what should be done. The abscess should be searched for and found, no matter what the stage in its development may be. It has been my routine under such conditions, if I think that the patient harbors an abscess but am not sure, to make a preliminary trephine over that area in the brain in which the abscess was believed to be situated. Then, if and when the crisis might occur, it would be possible with the least possible loss of time to evacuate the pus. As far as tapping of the abscess is concerned, there again I am in entire accord with Dr. Sachs. I have had five cases in which tapping has been done without the insertion of a drain, and four of the patients recovered. That a simple tap without the insertion of a drain is successful simply bears out the point that I tried to emphasize in the paper; namely, that it is the use of the minimum of trauma in the evacuation of pus that is of great importance. In these cases of abscess the patients are much more likely to die from the spread of cerebritis following the rough and fumbling insertion of a drain than they are from any other cause. By clumsy manipulation at the time the abscess is drained, the infection may easily be spread out into normal brain tissue. As a result, the defense mechanism of the brain must again attempt to localize the infection and is handicapped by the presence of the drainage tube. I would repeat, therefore, that to insure successful results it is important to avoid all possible trauma in the insertion of a drain. With regard to the high percentage of correct localization of abscess, I was as surprised at this as was Dr. Sachs, but I feel that by delay and carefully repeated examinations one is able to make a shrewd guess as to the presence and position of the lesion.

THE TREATMENT OF PERNICIOUS ANEMIA WITH DIGESTED LIVER

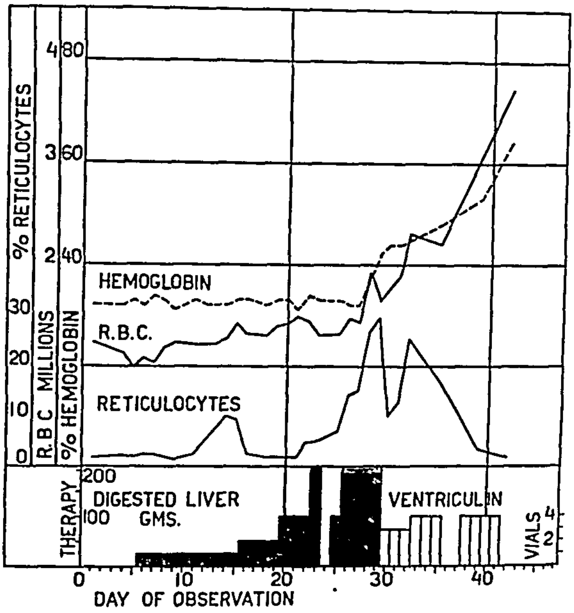
C. W. BARNETT, M.D.
AND
W. M. THEBAUT, Jr., A.B.
SAN FRANCISCO

Since the work of Minot and Murphy,[1] in 1926, the presence of a substance in liver, effective in producing remissions in pernicious anemia, has been repeatedly demonstrated. More recently, Castle[2] has shown that the digestion of beef in normal gastric juice leads to the formation of an effective substance, possibly identical with that present in liver. The nature of the substance in beef responsible for this reaction is not definitely known but it is conceivable that the same substance may also be present in liver, in addition to the effective agent already there. If so, the digestion of liver with normal gastric juice should give a material more potent in pernicious anemia than whole liver.

Walden and Clowes[3] have succeeded in increasing the potency of liver by mixing it with stomach tissue. The details of the method have not been published, but they mention that they had some preliminary difficulty in obtaining a potent product. Reimann[4] has also reported marked increases in the potency of liver by digestion in normal gastric juice obtained after histamine stimulation. He succeeded in obtaining typical remissions in pernicious anemia with as little as 10 Gm. of digested liver daily. Some time ago we carried out an experiment similar to the experiments of Reimann but did not report the results. In view of the disagreement between our results and those of Reimann, it seems worth while to record the experiment. The response of a patient with typical pernicious anemia to treatment with digested liver is shown in the accompanying chart. The digestion was carried out by the method of Castle and Townsend,[2] finely ground liver and normal gastric juice, obtained from a number of normal subjects after the subcutaneous injection of histamine, was used. The amounts of liver used are shown in the scale on the left side of the chart. The quantities of gastric juice varied from 120 to 160 cc. per hundred grams of liver. Treatment was started with 25 Gm. of liver daily for ten days. During this treatment there was a slight increase in reticulocytes to about 10 per cent but no change in the red cells or hemoglobin. The dose of liver was then increased to 50 Gm., 100 Gm. and finally 200 Gm. daily. No definite response was noted until the dose of 200 Gm. was reached, when a typical remission occurred. Treatment was then carried on with desiccated hog stomach. This response differs in no way from what one would expect after the feeding of the same amounts of whole liver. There is no evidence, from these results, that digestion has any effect on the potency of liver in producing remissions in pernicious anemia.

Since there are two possible sources of the effective substance in the mixture used, it is not possible to tell whether that already present in the liver or that formed by the digestion was responsible for the remission. In the latter case, since there was no apparent increase in potency, the destruction of that already present would have to be assumed.

To determine the effect of digestion on the effective substance already present in liver, a second patient with pernicious anemia was treated with a single dose of twenty-four vials of liver extract No. 343 digested in 120 cc. of normal gastric juice in the same manner in which digestion of the liver was carried out. The initial red count was 895,000, the hemoglobin 19 per cent and the reticulocytes 2.8 per cent. The reticulocytes increased to 35.2 per cent on the fifth day and the red count to 2,050,000 and the hemoglobin to 38 per cent on the tenth day. This response is exactly what one would expect from twenty-four vials of untreated liver extract. The antianemic factor in liver is evidently not destroyed by digestion.



The response of a patient with pernicious anemia to treatment with digested liver

SUMMARY

The response of certain patients with pernicious anemia to treatment with liver and liver extract digested in normal gastric juice differs in no particular from what would be expected from the same quantities of liver and liver extract, undigested.

These results suggest that the increase in potency of liver when mixed with stomach tissue observed by Walden and Clowes is not alone a result of digestion of liver protein but may be due to a summation of the potent material already present in liver, in stomach tissue and possibly small amounts formed by digestion. We are unable to explain the discrepancy between our results and those of Reimann.

BOTULISM IN NORTH DAKOTA

REPORT OF OUTBREAK OF THIRTEEN FATAL CASES

ROBERT W. ALLEN, M.D.
State Epidemiologist
AND
A. WALTER ECKLUND, M.S.
Bacteriologist in Charge, State Public Health Laboratory
BISMARCK, N. D.

In reviewing one of the early biennial reports of the North Dakota State Board of Health we find that an outbreak of so-called ptomaine poisoning occurred at Mayville in June, 1895. The victims, all of whom died, had eaten some canned cove oysters from the same can, and all of those who had eaten of the oysters were affected. The symptoms recorded were:

> Disturbed vision, swollen tongue, difficulty in speaking and swallowing, the latter increasing until patient was unable to swallow at all. Complete paralysis of pharyngeal and esophageal muscles for several hours before death. Heart action toward end feeble. Duration forty to sixty hours.

In the light of present knowledge, these were undoubtedly cases of botulism.

The first recorded outbreak of botulism in North Dakota occurred in June, 1930, at Golva, Golden Valley County, with four fatal cases reported. North Dakota suffered its second reported outbreak of botulism in 1931, which incidentally was the largest outbreak ever to occur in this country in a single community from a single common cause, and occurred within eight months after the outbreak at Golva.

A midnight lunch consisting of buns, hot boiled wieners, vegetable salad, light spice cake, light cookies and coffee was served in connection with a party given at a farm home near Grafton, Walsh County, on the evening of Jan. 29, 1931. The salad consisted of diced carrots, peas and cut string beans, served on a lettuce leaf, with whipped cream dressing. The carrots, peas and string beans were from a "batch" home canned the previous season by the so-called cold pack method, a copper wash boiler having been used instead of a pressure cooker. The canning receptacles used were glass jars with both metal and glass caps. The host family had been eating of this "batch" of vegetables during the fall and winter without previous ill effects. A history of disease among the animals or poultry on the farm was not obtainable.

Sixteen of the seventeen present partook of the entire lunch, one guest declining to eat the salad because he never ate vegetables in any form; subsequently he did not become ill. Thirteen of the sixteen who ate of the salad afterward became ill and died. The remaining three who ate of the salad and did not subsequently become ill therefrom were intoxicated at the time of eating, had been nauseated and vomited before lunch was served, and vomited again during or just after lunch. "Moon" or "hootch," home-made beer, and wine were the liquors consumed by several who attended the party. It did not enter into the cause of death, however, as five of the victims who died did not take a drink of liquor in any form.

The ages of the patients ranged from 15 to 45 years. The time intervening between the ingestion of the poisoned food and the onset of the disease ranged from 16 to 108 hours, with an average of 31.8 hours. The duration of the disease ranged from 12 to 120 hours, with an average of 34.5 hours.

REPORT OF CASES

The first victim was a housewife, white, aged 38. The onset took place sixteen hours after ingestion of the poisoned food. This patient had eaten a double portion of the salad, her husband having refused his portion because he never ate vegetables in any form. The symptoms in the order of their appearance were dizziness, muscular weakness, diplopia, vomiting, constipation, difficulty in swallowing, muscular paralysis (she could not help herself in bed); respiration was normal in rate but very superficial; the patient appeared toxic and said but little; the pulse rate was 80 until during the last hour and then became rapid up to 120-140. The temperature was normal; blood pressure 125 systolic and 75 diastolic; reflexes were normal; the pupils equal. Death occurred forty-eight hours after ingestion of the poisoned food and thirty-two hours after the onset of the disease; there was marked quietude, no struggle and extreme cyanosis. The pulse was perceptible for several minutes after respirations ceased. The immediate cause of death was respiratory paralysis.

The twelfth victim was a white man, aged 26, single, who did general labor. The onset occurred thirty hours after ingestion of the poisoned food. On arising in the morning, he complained of dizziness and diplopia and was nauseated. Throughout the entire day the same symptoms persisted but did not increase. Diarrhea followed an oil cathartic. Twenty-four hours after the onset he complained of difficulty in swallowing and talking; the tongue was "thick." The blood pressure was 115 systolic and 70 diastolic, pulse 80, temperature normal. There was no muscular weakness until the afternoon of the second day. He slept well the first night, with no illness except for the diarrhea, but he became restless the second night and remained so until death. There was labored respiration in the afternoon of the second day and he was unable to extend the tongue from the mouth. Forty-eight hours after the onset he suffered choking spells, later strangling frequently. Cyanosis developed. The sensorium was clear. Death occurred fifty-two hours after the onset of the first symptoms. The immediate cause was respiratory paralysis. The pulse rate shortly before death was 100 and the temperature was subnormal. The pulse continued strong for several minutes after respirations ceased.

The last victim was a white man, aged 23, single, a laborer. The onset of symptoms occurred 108 hours following ingestion of the poisoned food. There was muscular weakness; he fell down and was unable to arise. Visual disturbance appeared on the second day of illness and consisted of blurred vision only. During the first three days of illness he was about town, attended the funerals of his fellow victims, testified before the coroner's hearing, and was interviewed by one of us and by other investigators. He first experienced difficulty in swallowing solids on the third day of illness but had no difficulty in swallowing liquids at any time. Muscular weakness was pronounced on the third day. He refused hospitalization. On the fourth day, while running down an alley in response to a volunteer fire call, he fell; being unable to arise, he was picked up by friends and taken to the hospital. Muscular weakness was marked; he was unable to turn himself in bed without great difficulty. The sensorium was clear until death. He was restless most of the time and slept poorly. Respiration was rapid but quiet, superficial but not labored. The pulse was from 100 to 140, gradually increasing up to the time of death. The temperature was from 100 to 102 F. The blood pressure was 110 systolic and 70 diastolic. The urine was normal. Death occurred suddenly from respiratory paralysis, five minutes after the patient had sat up in bed and taken liquid nourishment (a bowl of soup), 120 hours after the onset of symptoms. There was little cyanosis and no struggling.

COMMENT

The general symptoms, elicited by other victims with few exceptions, were as follows: 1. Diplopia followed blurred vision, changing to dimness of vision. 2. There was difficulty in speech proceeding to complete aphonia. 3. Constipation was the rule; some of the victims failed to be relieved with all available measures, while one suffered diarrhea with green paint-like stools. 4. The patients were unable to protrude the tongue beyond the teeth and to expel accumulated mucus from the throat. 5. Most of the patients evinced restlessness and intense fear of death. 6. The temperature was subnormal in all but two cases. 7. One of the attending physicians described the appearance of the throats as similar to one anesthetized locally for tonsillectomy. 8. Death was due to strangulation or respiratory paralysis in all cases. Heart action continued in one case for six minutes after the respirations ceased.

POISONED FOOD INVOLVED

Unfortunately, none of the original salad material was obtainable. However, the vegetable mixture of diced carrots, peas and cut string beans, which entered into the formation of the salad, was undoubtedly the infected food. This conclusion is arrived at by the process of elimination. The wieners and lettuce were the only other foods that could have entered into the cause. The wieners were from a batch of some 150 pounds, made up by the local meat market two days previously and sold indiscriminately to the local trade. The lettuce had been purchased on the open market. No other food poisoning cases occurred in the community except among those who attended the party and ate of the lunch served at midnight. The wieners had been boiled just previous to being served, which would have rendered them safe even though they had been infected. In addition, two younger children of the host family, who had retired before lunch was served, ate some of the remaining wieners for breakfast the following morning and for lunch at school that day, without ill effects. Alcoholic beverages consumed were ruled out for the reason that five of the victims did not drink at all, and of those who did, three did not become ill.

E. M. Stanton, Regulatory Dept., Bismarck	Gram-positive rods; no spores	Negative for guinea-pig and chickens	Negative for guinea-pig	Negative	None submitted	None submitted

Samples of the suspected food were secured from the host's family larder and sent to the State Public Health Laboratories at Grand Forks and Bismarck, to the State Regulatory Department, Bismarck, to the Agricultural College, Fargo, and to the University of Chicago Laboratory, Chicago. A summary of the reports of the various laboratories is given in the table.

LABORATORY EXAMINATIONS

As already stated, specimens of the suspected canned vegetables were secured for a bacteriologic examination and sent to five different laboratories. Four jars of the mixture of diced carrots, peas and cut string beans were secured from the pantry and cellar, from the same supply as the vegetables used for the salad.

The material in the jars was a juice of the vegetables together with solid portions of them. The liquid was cloudy and the contents of the jars gave off a sour, rancid, limburger cheese-like odor. There was visible gas production. The five laboratories to which the samples were submitted followed in general the same technical methods of procedure for isolation and identification of Bacillus botulinus and its toxin, namely:

1. Direct microscopic examination of material.
2. Toxicity tests on the original material.
   (*a*) Inoculation.
   (*b*) Feeding.
3. Cultural examination for B. botulinus.
4. Toxicity test of the cultures.

In addition to these procedures, Dr. W. E. Carey of the University of Chicago secured specimens of spinal fluid, blood and a section of the ascending and transverse colon, with its contents, from the twelfth victim. These were taken to the University of Chicago, Department of Hygiene and Bacteriology, for study. A comparative summary of the reports of the various laboratories is given in the accompanying table.

An evaluation of the laboratory results is rather difficult to make. In general, the results agree quite closely. A gram-positive spore bearer was found by two laboratories, a gram-positive rod by one, two laboratories not reporting this examination. A general agreement of four laboratories on feeding test with guinea-pigs, chickens and mice indicates that the samples were nontoxic by this method. Three laboratories reported the material nontoxic by subcutaneous or intraperitoneal injection. One laboratory found the material toxic but did not carry out antitoxin protection tests. All five laboratories were in agreement that the material did not contain B. botulinus as indicated by the cultures made of the original materials. This of necessity removes the possibility that the one laboratory reporting the original food toxic had found the toxin of B. botulinus. There can be only two interpretations of the laboratory work done on the toxicity of the food and its bacterial flora:

1. The material submitted and examined was not the same as the material consumed at the host home.

2. The material under examination was nontoxic and the laboratory reports do not substantiate the hypothesis of a food infection with B. botulinus.

Only one laboratory received clinical material for examination, this consisting of blood, spinal fluid and a section of colon from the twelfth victim. The blood and spinal fluid were nontoxic. The report of the bacteriologic examination of the contents of the colon was reported as follows:

> Several cultures were made from the section of the colon. One of these, on feeding to guinea-pigs, was found to be toxic.

Protection tests with antitoxins A and B gave protection with type A antitoxin but not with type B. This demonstrates the presence of B. botulinus type A in the intestine of one of the victims and it indicates the Grafton outbreak was due to type A botulinus.

This one single factor is all that the laboratories offer to substantiate the clinical diagnosis of botulism. Even though this seems rather meager evidence, the fact cannot be overlooked that B. botulinus type A was isolated from the intestine of one of the victims, in spite of the fact that the food examined was unquestionably nontoxic.

NECROPSY

The macroscopic and histopathologic observations on the twelfth victim, as noted by Drs. French and Saiki of the University of North Dakota School of Medicine, Grand Forks, were confirmatory of botulism intoxication. General congestion of all internal organs was noted, especially those of the central nervous system. The basal ganglion showed slight congestion, with chromatolysis of the ganglionic cells and disappearance of Nissl granules.

No specific pathologic changes in bodies dead from botulism have been definitely recognized in the past. The observations in this case, however, are in close harmony with observations on record of former cases. All, therefore, strongly support the clinical diagnosis of botulism poisoning.

DIAGNOSIS

The diagnosis of botulism, although a rare disease, from the clinical symptoms alone, when established, entails no serious entanglements to the trained mind of the skilled physician. Dr. M. W. Lyons of Sentinel Butte, who attended the four patients of our first recorded outbreak, and Drs. G. M. and C. J. Glaspel, C. R. Thompkins and F. W. Deason of Grafton, who attended the patients of the second and most recent outbreak, made positive diagnoses of botulism prior to the death of the first victim. Not one of these physicians had previously seen a case of botulism.

TREATMENT

General.—The general treatment carried out was that of heavy catharsis, forced liquids, rest in bed, liquid diet, and, toward the end, respiratory and cardiac stimulants. Sedatives were required in some cases. All patients were hospitalized or under a nurse's care in their home.

Specific.—Specific treatment with botulinus antitoxin was not resorted to either prophylactically or therapeutically, for the reason that it was not available until twelve of the victims were dead and the thirteenth already ill, and the available supply was insufficient to offer any therapeutic advantage.

Antitoxin.—Botulinus antitoxin type A and B combined, as supplied by Jensen and Salisbury, Inc., Kansas City, Mo., sole commercial manufacturers of the product in the United States, was administered to one of the three survivors on the eleventh day following the fatal party. The attending physician, W. H. Long, from the Dakota Clinic, Fargo, kindly furnished the following report:

> The ocular movements were good, the pharyngeal reflexes normal; there was a definite nystagmus to the right, to the left and vertically. The temperature was normal, the pulse 80.
>
> It was thought best to give the antitoxin, so the patient was tested by the intradermal method and then given 1 cc. of the antitoxin. After half an hour, the remainder of the 1,000 units was given. That night she was very ill; her legs were weak and she fainted while climbing the stairs to retire. I saw her the following day and the nystagmus was much increased, but there were no other symptoms. On the second day the nystagmus was still present, and on the fourth day she developed a mild serum reaction. Subsequently the patient completely recovered.

SUMMARY

1. Diagnosis of botulism, type A in the Grafton outbreak was confirmed by the University of Chicago laboratory, from a section of the colon of one of the victims.

2. The vegetable mixture of diced carrots, peas and cut string beans served in the salad was without doubt the poisoned food. This is concluded from the elimination of all other possible poisoned food and the suggestive laboratory observations on other similar canned vegetables.

RECOMMENDATIONS

1. The proper procedure in home canning of foodstuffs and their preparation before serving should be given the greatest possible publicity.

2. In case of an outbreak of botulism, all individuals known or suspected to have eaten of the poisoned food should receive a preventative dose of botulinus antitoxin, type A and B combined, at the earliest possible moment.

3. As the immediate cause of death in botulism is respiratory paralysis, it would seem feasible that artificial respiration or the use of a respirator should be resorted to in the last measure of treatment, in conjunction with the free use of botulinus antitoxin.

Clinical Notes, Suggestions and New Instruments

SUCTION IN OBTAINING ENDOMETRIAL BIOPSIES

HAROLD H. KLINGLER, M.D., AND JOHN C. BURCH, M.D.
NASHVILLE, TENN.

The diagnosis of intra-uterine lesions is frequently difficult and in many cases can be established only by the study of material obtained by curettage. In a recent study of endometrial hyperplasia it seemed desirable to obtain tissue from each patient at weekly intervals during the course of the disordered cycle. It was, of course, impossible to curet so frequently, and, furthermore, such tissue would have no value from the standpoint of study, as it would be impossible to gage the factor of regeneration.

Geist's[1] method of studying the morphology of menstrual blood had seemed a solution in cases in which actual bleeding occurred. In a case of this type, in which the cervix was open, we inserted a small catheter into the uterus and aspirated the bloody uterine contents. In this instance a sufficient quantity of tissue was obtained to indicate that endometrium was actually sucked into the catheter. Martin and Ellis[2] and others had previously used the principle of aspiration and needle puncture in obtaining tissue from deep-seated lesions, but, so far as we can determine, the method of aspiration has not been applied to the uterus. It is not, however, our intention to claim priority but simply to call attention to a method that has proved useful to us.

The method is as follows:

An ordinary Keyes-Ultzman cannula, which in reality is nothing more than a rigid hollow uterine sound with perforations at the tip, was used. Its use has been reported in a previous communication.[3]

From the Department of Obstetrics and Gynecology, Vanderbilt University School of Medicine.

[1] Geist, S. H.: Morphology of Menstrual Blood, Am. J. Obst. & Gynec. **22**: 532-542 (Oct.) 1931.

[2] Martin, H. E., and Ellis, E. B.: Biopsy by Needle Puncture and Aspiration, Ann. Surg. **92**: 169 (Aug.) 1930.

[3] Burch, J. C., and Klingler, H. H.: Endometrial Biopsy by Suction, J. Tennessee M. A., to be published.

While the results with this instrument have proved satisfactory in a number of cases, it was frequently difficult to insert the instrument on account of its rigidity. A Luer or all-glass type syringe was attached to the cannula. However, numerous syringes were broken in withdrawal and suction due to the stress at the junction of syringe and cannula. This made it necessary to substitute a tube constructed of malleable copper and attached to a record syringe. Another instrument, also made of copper but with a small curet with closed back, was also constructed. We were not able to obtain good results with the curet head. The simple copper tube, however, has given excellent results and has been in use in the outpatient department for some time. No bad results have been noted. Most patients complain of mild discomfort, but in no instance has an anesthetic or analgesic been necessary.

The technic is briefly as follows: The patient is placed in the lithotomy position. Cervical exposure is obtained by means of a bivalve speculum. The cervix is cleansed of mucus and the os painted with mercurochrome-220 soluble. The tube is inserted into the uterus and bent slightly, depending on its position. When the cannula comes to rest against the uterine wall, the syringe is attached to the cannula and strong suction is made, while slight pressure keeps the tip of the cannula in contact with the uterine mucosa. While suction is maintained, the cannula is withdrawn for about half an inch and then released. The instrument is then rotated slightly, so that on reinsertion it will come to rest on another part of the mucosa. This process is usually repeated about three times, and the instrument withdrawn during continuous suction. The apparatus is carefully washed with solution of formaldehyde by drawing the fixative back and forth several times in order to remove all the particles of tissue from the apparatus. It is then carefully washed out and sterilized and is ready for use again.

We believe that as much information can be obtained by this method as by diagnostic curettage, except in cases of very small early circumscribed endometrial carcinoma. This condition should always be thought of when the symptoms are not in accord with the study of the curettings or when the results of treatment are unsatisfactory. In such instances, curettage should be performed without delay.

CONTACT DERMATITIS IN AN ANESTHETIST, DUE TO "AVERTIN" (TRIBROM-ETHANOL)

George V. Kulchar, M.D., Philadelphia

Since the introduction of "Avertin" in 1925 it has been used extensively as a general anesthetic. Numerous reports have appeared describing renal and hepatic damage following its use. Further studies have shown, however, that the impairment of renal and hepatic function is for the most part slight and transient. This has been substantiated by the recent work of Bruger, Bourne and Dreyer.[1] There have been, however, no reports of toxic eruptions directly attributable to "Avertin," and the case reported here of cutaneous sensitization following repeated prolonged exposure in the handling of the drug by an anesthetist is the first to come to my attention. Survey of the literature seems to indicate that "Avertin" as an anesthetic will probably come into even more extensive use in the future, owing to its relative safety and ease of administration.

In this country "Avertin" is dispensed in the form of "Avertin Fluid." This is a 100 per cent solution of tribromethyl alcohol (Avertin) in amylene hydrate. For the induction of anesthesia, a 3 per cent solution of the "Avertin Fluid" is made up in water at 40 C. This is instilled rectally by means of a tube. Owing to the very labile molecular structure of tribromethyl alcohol, heating above 45 C. results in the formation of dibromacetaldehyde and hydrobromic acid. The former appearing in improperly prepared solutions gave rise to numerous instances of rectal irritation reported following the introduction of "Avertin." The presence of dibromacetaldehyde is now tested for as a routine with congo red before instillation. With this precaution, the instances of irritation have greatly decreased. It seems unlikely that these represent true instances of sensitization to the drug.

REPORT OF CASE

Miss N. M., aged 28, an anesthetist, was seen on Nov. 27, 1931, at which time the dorsal and volar surfaces of all the fingers and the palms of both hands were deeply erythematous, fissured and exfoliating. No vesiculation was noted and the nails appeared normal. Careful inquiry into the family and past histories revealed nothing of importance. The patient had been administering "Avertin" as an anesthetic extensively for the past twelve months. For the past six weeks she had noted itching and burning of the fingers and palms whenever exposed to "Avertin," and the eruption had been present four weeks. There had been no previous dermatitis, although exposure had been repeated and prolonged prior to the onset of the present eruption. On physical examination, nothing abnormal was noted except for the dermatitis of the hands. Close inspection of the feet and intertriginous areas revealed no evidence of a mycotic infection. Scrapings made from the fingers were negative for fungi. The blood Wassermann reaction was negative.

Because of the itching and burning noted by the patient after handling the "Avertin Fluid" and the accentuation of the process on the fingers handling the rectal tube, a sensitization was suspected. According to the method described by Jadassohn,[2] patch tests were made with the fluid in dilutions varying from 25 to 100 per cent. After forty-eight hours definite positive reactions, consisting of an erythematous miliary papular eruption localized to the area of application, were noted with all dilutions. The controls were negative. Within forty-eight hours after the removal of the patch tests, the eruption became vesicular. The positive reactions persisted for eight days, the late stages resembling a chronic eczematoid dermatitis. On repetition of the patch tests the same results were obtained, a brawny indurated plaque resulting from one application. During the repetition the patient chanced to sleep with her forehead resting on a patch test being made with 50 per cent solution of "Avertin Fluid." Two days later a miliary papular eruption appeared over the contact area on the forehead. In order to determine whether the "Avertin" or its solvent, amylene hydrate, was the cause of the sensitization, patch tests were made with the latter in the same dilutions. These were negative.

The patient was instructed to use rubber gloves over cotton gloves in making up and administering the anesthetic, a precaution heretofore not observed. Following the use of a 6 per cent crude coal tar ointment and small doses of x-rays, and the protective measures, the eruption cleared up in three weeks. Exposure to extremely minute amounts of "Avertin," as, for example, the handling of her operating room gown without gloves, has, however, resulted in definite recurrences. These have cleared up on the resumption of protective measures. Attempts at desensitization with crystalline Avertin itself were contemplated but have not been done, as the patient is at the present time free from eruption under the precautions observed.

With "Avertin Fluid" in dilutions of 25, 50 and 100 per cent, patch tests were made on a series of ten patients attending the clinic because of nonallergic dermatoses. In one instance a mildly positive reaction was noted with a 100 per cent solution in a patient who gave no history of exposure to the drug. A patch test with amylene hydrate was negative on this patient.

With the patient's serum taken at the time of the eruption, attempts were made at passive transfer, a slight modification of the Prausnitz-Küstner[3] method being used. This consisted of the application of the antigen to the site of the injection of the sensitive patient's serum as a patch rather than a scratch or intradermal test. Attempts made in three patients were unsuccessful.

As has been pointed out by Kesten and Laszlo,[4] occupational dermatitis and dermatitis venenata in most instances result from a local cellular sensitization to specific nonproteins acquired by previous contact. The contact with the sensitizing substance is often long and repeated before evidence of sensitization appears. Attempts to demonstrate circulating antibodies, however, by the passive transfer method in sensitized patients have

---

[4] Kesten, Beatrice, and Laszlo, Elizabeth: *Dermatitis Due to Sensitization to Contact Substances*, Arch. Dermat. & Syph. **23:** 221-237 (Feb.) 1931.

given uniformly negative results. In the case reported, the exposure to the sensitizing agent, "Avertin," had been repeated and prolonged over a period of eleven months before any evidence of sensitization appeared. As the sensitization is probably confined to the cells of the epidermis, the attempts to demonstrate general sensitization by passive transfer methods would be expected to yield negative results.

SUMMARY

A case of contact dermatitis occurred in an anesthetist due to acquired local sensitization to "Avertin" (tribromethyl alcohol), a drug used for general anesthesia. Attempts at passive transfer were unsuccessful, the sensitiveness being established by patch test.

A PUMP AND MANOMETER FOR ADMINISTERING ARTIFICIAL PNEUMOTHORAX

T. T. Wang, M.D., and C. M. Van Allen, M.D.
Peiping, China

This instrument has been used by us for induction of pneumothorax in 30 cases of pulmonary tuberculosis and for refills of air on more than 553 occasions. It is preferred to the standard types of apparatus for giving artificial pneumothorax, which employ columns of water in bottles to displace air into the chest, because it is smaller, the operation is simpler, the air is under much more delicate control, the intrapleural pressure may be read more conveniently during the introduction of air, and the U-tube of the manometer is filled and refilled with water more easily. The pump can be used for various other clinical purposes as well, since it is capable of driving efficiently either gases or fluids.

The mechanical details of the pump have been described elsewhere,[1] and it is necessary here to point out only the chief characteristics. The pump consists of a wheel 14 cm. in diameter mounted vertically on a base, with shaft and bearings. A driving handle is attached to the shaft. A number of rollers are mounted at regular intervals along the periphery of the wheel, and they meet and press against a rubber tube, which lies in a semicircular track below the wheel and is fastened to short metal tubes at both ends of the track. Each metal tube has two arms for outside connections, one of which extends to the back and is guarded by a stopcock. An automatic counter records the number of revolutions of the wheel. Pumping is accomplished by turning the handle: the rollers drive the air in the tube ahead continuously and the elastic recoil of the tube draws more air in behind. The direction of pumping can be reversed merely by turning the handle backward. All parts of the pump except the rubber tube are metallic and durable, and the tube can be renewed easily.

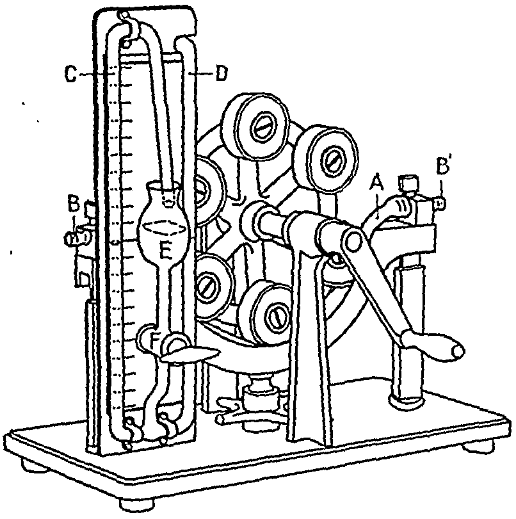

Fig. 1.—Front oblique view. The pump is shown partly covered on the left by the manometer. *A* indicates the rubber tube, which is compressed by the rollers, and *B* and *B'* the metal tubes to which it fastens. *B* serves for connection of the rubber tube leading to the pneumothorax needle (not shown). *C* and *D* are the distal and proximal limbs, respectively, of the U-tube of the manometer. *E* is the reservoir and *F* the stopcock for filling the U-tube.

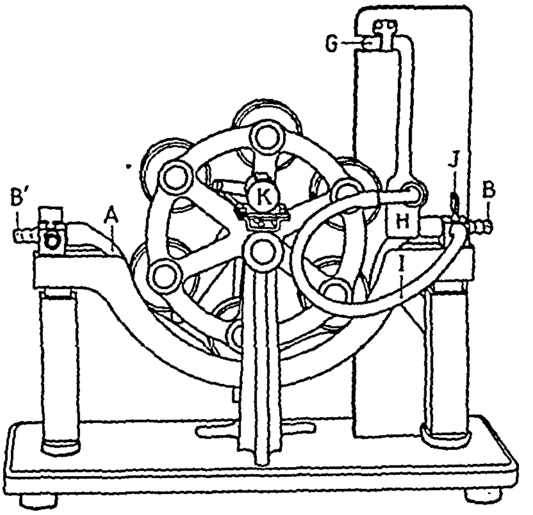

Fig. 2.—Back view. *A*, *B* and *B'* are the same as in figure 1. The proximal limb of the U-tube of the manometer appears at *G* from the front. *H* is the trap and *I* the connection to the side arm of tube, *B'*. *J* is the stopcock guarding that arm. *K* is the automatic counter.

The manometer is described here for the first time. It is carried on the left side of the pump. A small reservoir occupies the center of the manometer, with connection below to the bend and above to the distal limb of the U-tube. A stopcock is situated in the connection below the reservoir. The proximal limb of the U-tube passes above to a trap on the back of the manometer, the trap being connected in turn to the back arm of the metal tube on the same side of the pump. An adjustable scale lies behind the distal limb of the U-tube, with graduations reading from + 20 to — 20 cm. of water pressure.

The pump is calibrated simply, as follows: The stopcocks of both metal tubes are turned off and a piece of rubber tubing is attached to each of the two free arms of those tubes. The rubber tube on the right is led to water in a flask, while that on the left is led to an empty graduated cylinder. Pumping is then started, and the moment that water begins to appear in the cylinder the automatic counter is set at zero. Pumping is continued until a certain large amount of water has been displaced, for example, 500 cc. The number of revolutions is now read and the displacement per revolution, or per hundred revolutions, is calculated. This figure is applicable with sufficient accuracy in estimating the amount of air delivered for pneumothorax. Recalibration is necessary only at intervals of one or two months. The manometer is prepared for use by pouring water into the reservoir until full, opening the stopcock below the reservoir to allow the U-tube to fill, and closing the stopcock when the fluid levels in the U-tube reach the zero mark of the scale. Slight further adjustment can be made if necessary by sliding the scale up or down. At any time that the water in the U-tube is accidentally thrown out through the distal limb because of a sudden increase of pressure, it is automatically caught in the chamber and can be used again. Should the water be displaced from the U-tube in the opposite direction, it is caught in the trap and prevented from reaching the patient.

Additional apparatus consists in a pneumothorax needle of standard pattern and a few feet of rubber tubing to connect the needle to the free arm of the left metal tube of the pump. This rubber tubing is in two sections, joined together by a short glass tube filled with loosely packed cotton, and the cotton serves to filter the air. The needle and the section of tube next to it are the only parts that need to be sterile. With these attachments made, the counter is set at zero, the stopcock on the

---

A few of these instruments may be obtained from the Peiping Union Medical College, Precision Shop.

[1] Van Allen, C. M.: A Pump for Clinical and Laboratory Purposes Which Employs the Milking Principle, J. A. M. A. **98**: 1805 (May 21) 1932.

left metal tube is opened, and the needle is inserted in the chest wall. Arrival of the needle's point in the pleural cavity is indicated by characteristic oscillations of the water in the manometer. Without further adjustment, pumping is begun and carried on at an appropriate rate. It is stopped momentarily at any time that the intrapleural pressures require reading, since the manometric values during pumping are necessarily slightly elevated and only a moment of rest is required for equalization. A series of many readings is secured in each case, so that the changes in pressure during administration can be used as one of the guides for determining the amount of air to be given.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

W. A. Puckner, Secretary.

TRIPHAL.—A product consisting essentially of sodium aurothiobenzimidazole carboxylate, $C_6H_3N{:}NHCSAu.COONa$, with a small amount of a product of indefinite composition. The sodium salt of a compound formed by the interaction of gold halides with thiobenzimidazole carboxylic acid. Triphal contains from 44 to 47 per cent of gold.

Actions and Uses.—Proposed for use as a gold salt in the treatment of lupus erythematosus. Foci of infection, if present, should be removed before beginning treatment with triphal. It is contraindicated in pregnancy, kidney disease, acute progressive pulmonary tuberculosis and intestinal tuberculosis. Patients receiving triphal should be kept away from strong sunlight and should receive no actinotherapy. Generalized pruritus may result from idiosyncrasy or metallic retention. The development of erythema or albuminuria indicates intolerance to the drug; on its appearance triphal should be discontinued and intravenous injections of sodium thiosulphate instituted.

Dosage.—For adults, initial dose, intravenously, 0.025 Gm. (3/8 grain), the dose being gradually increased to 0.1 Gm. (1½ grains) for children, average initial dose, 0.01 Gm. (1/6 grain), gradually increased, if possible, to 0.025 Gm. (3/8 grain) three times weekly.

Manufactured by H A. Metz Laboratories, Inc., New York. U. S. patent 1,558,584 (Oct. 27, 1925; expires 1942). U. S. trademark 188,475.

Ampules Triphal, 0.025 Gm.

Ampules Triphal, 0.1 Gm.

Triphal occurs as a light yellow, odorless powder, readily soluble in cold water, insoluble in alcohol and ether. An aqueous solution of Triphal is slightly alkaline in reaction, is stable for only a short time, and is readily decomposed by heat. On addition of mineral acids to solution, a precipitate is produced, soluble on addition of excess alkali solution.

Dissolve 0.1 Gm. triphal in 1 cc. water; a clear solution results. Transfer 1 cc. of triphal solution (1: 200) to a clean test tube containing a freshly prepared solution of sodium stannite (prepared by adding sufficient stannous chloride slowly to 2 cc. of dekanormal sodium hydroxide solution, until the precipitate barely dissolves). Gently heat the solution to the boiling point; a metallic mirror is formed. To 3 cc. of solution (1: 200) add 1 cc. dekanormal sodium hydroxide solution and 0.15 cc. freshly prepared phenylhydrazine hydrochloride solution (1: 10); a blue color is produced, which appears reddish in reflected light. To 4 cc. of the solution (1: 200) add 0.15 cc. alkaline mercuric potassium iodide solution; a pronounced yellowish color is produced. Dissolve 0.1 Gm. of triphal in 3 cc. water, add 0.2 cc. of diluted acetic acid, and filter; the filtrate shows no brown coloration after adding 0.1 cc. of sodium sulphide solution. To 2 cc. of solution (1: 50) add 0.2 cc. diluted nitric acid and filter; to one half of the filtrate add 0.2 cc. barium nitrate solution; no precipitate occurs (*sulphate*); to the other portion of acidified solution add silver nitrate solution; not more than a faint turbidity appears (*halides*). To 4 cc. of triphal solution (1: 100) add 0.2 cc. sodium nitrite solution and 0.2 cc. diluted hydrochloric acid, followed by the addition of sufficient betanaphthol solution (0.01 Gm. in 5 cc. of sodium hydroxide solution) that the precipitate formed redissolves; no red color appears. Ignite 0.1 Gm. of triphal in a porcelain crucible, extract the residue with normal hydrochloric acid, and filter; the filtrate gives a characteristic sodium flame test and yields a white precipitate with a solution of barium chloride.

Dry about 0.1 Gm. of triphal, accurately weighed, for eight hours at 100 C. The loss in weight should not be more than 8.0 per cent nor less than 6.0 per cent of sample weight.

Transfer approximately 0.2 Gm. triphal, accurately weighed, into a tared porcelain crucible, and ignite well at red heat. Extract the residue with six 5 cc. portions of normal hydrochloric acid solution; filter each portion through an ashless filter paper. Transfer the remaining residue to the filter and wash with five 3 cc. portions of water. Transfer filter and residue to crucible, dry, and ignite to constant weight. The weight of the residue corresponds to not more than 50.0 per cent and not less than 47.8 per cent of gold, calculated to the dried basis.

LIVER MEAL.—A mixture containing desiccated beef liver 81 per cent, malted milk 18 per cent, and powdered cinnamon 1 per cent.

Actions and Uses.—Liver meal is prepared to meet the need of a concentrated liver diet in a form that is palatable and convenient.

Dosage.—For children, one heaping teaspoonful three times daily; for adults, two heaping teaspoonfuls three times daily. Liver meal may be added to milk, soups, cereals or fruit juices but should not be cooked or boiled.

Manufactured by the Livermeal Corporation, Hoboken, N. J. No U. S. patent or trademark.

To prepare liver meal, fresh beef liver is ground and then coagulated in air-tight kettles at a temperature of 82 C. The liver is dehydrated in vacuo and powdered. The malted milk and powdered cinnamon are then added and thoroughly mixed. The manufacture is so regulated that no batch is more than thirty days old when shipped. The malted milk used complies with the government standard and has approximately the following composition: carbohydrates, 71.22 per cent; proteins, 14.48 per cent; fat, 8.15 per cent; ash, 3.43 per cent, and water, 2.72 per cent.

Liver meal is a light brown powder having a slight odor and taste of liver.

SCARLET FEVER STREPTOCOCCUS ANTITOXIN (See New and Nonofficial Remedies, 1932, p. 364). The National Drug Co., Philadelphia.

Scarlet Fever Streptococcus Antitoxin Refined and Concentrated (National).—It is prepared by inoculating horses with scarlet fever streptococcus toxin and live virulent cultures of scarlet fever streptococci, under U. S. patent 1,547,369 (July 28, 1925; expires 1942) by license of the Scarlet Fever Committee, Inc. It is marketed in syringe packages of 2,000 units (prophylactic dose); in syringe packages of 6,000 units (therapeutic dose); also marketed in single 1 cc. vial packages (for the diagnostic blanching test) containing sufficient scarlet fever streptococcus antitoxin for five tests.

Committee on Foods

GENERAL COMMITTEE DECISIONS

The Committee on Foods authorizes the publication of the following General Committee Decision adopted for its own guidance and for that of food manufacturers and advertising agencies on food advertising.

Raymond Hertwig, Secretary.

VITAMIN AND MINERAL CONTENT OF DRIED VEGETABLES

To be acceptable, dried vegetables, either powdered or in other form, shall retain in highest degree possible with effective manufacturing methods the vitamin and mineral content of the raw vegetables. Products with materially reduced vitamin or mineral content may be accepted provided they are accompanied by labels and advertising prominently and appropriately declaring the vitamin or mineral content with respect to that of the natural vegetable used.

REPORTS OF THE COMMITTEE

The following products have been accepted by the Committee on Foods of the American Medical Association following any necessary corrections of the labels and advertising to conform to the Rules and Regulations. These products are approved for advertising in the publications of the American Medical Association, and for general promulgation to the public. They will be included in the Book of Accepted Foods to be published by the American Medical Association.

Raymond Hertwig, Secretary.

UFFELMANN'S RYE BREAD

Manufacturer.—The Uffelmann Baking Company, Cincinnati.

Description.—Rye bread made by the straight dough method (method described in The Journal, March 12, 1932, p. 889); prepared from "clear" wheat flour, white and dark rye flours, water, yeast, salt, caraway seed and a sour ferment consisting of dark rye flour and water.

Analysis (submitted by manufacturer).—

	per cent
Moisture (entire loaf)	36.8
Ash	1.9
Fat	1.5
Protein (N × 6.25)	9.9
Crude fiber	0.5
Carbohydrates other than crude fiber (by difference)	49.4

Calories.—2.5 per gram; 71 per ounce.

Claims of Manufacturer.—A rye bread of good quality.

MEAD'S FLORENA

(Partially Dextrinized Wheat Flour)

Manufacturer.—Mead Johnson and Company, Evansville, Ind.

Description.—Partially cooked and moderately baked patent wheat flour.

Manufacture.—Patent wheat flour in cotton bags is immersed in boiling water; a gelatinous surface layer is formed which prevents permeation of the water through the flour. The interior flour in a fairly dry condition is cooked for three hours. The bags are removed from the water and baked at a low temperature for five hours. The partial cooking and moderate baking rupture the starch granules and partially dextrinize the starch, thereby rendering the carbohydrate content more readily digestible.

During the baking, the gelatinous surface coating is changed into a hard crust. The bag and crust are removed and discarded. The inner portion of caked dried flour is ground to a fine powder of light tan color. The powder is again heated to reduce the moisture content and is packed in tin containers.

Analysis (submitted by manufacturer).—

	per cent
Moisture	4.5
Ash	0.5
Fat	1.0
Protein (N × 5.7)	9.2
Crude fiber	0.3
Dextrins (alcohol precipitation method)	6.0
Carbohydrates other than crude fiber (by difference)	84.5

Calories.—3.8 per gram; 108 per ounce.

Claims of Manufacturer.—A partially dextrinized wheat flour for use in infant feeding. Especially indicated (1) as a routine cereal diluent, (2) in cases of sugar intolerance, (3) as a base for "butter-flour mixtures," and (4) for high starch feedings.

GOLDEN KEY EVAPORATED MILK

Manufacturer.—Pet Milk Company, St. Louis.

Distributor.—Golden Key Milk Products Corp., St. Louis.

Description.—This is the same product as Pet Evaporated Milk (THE JOURNAL, Nov. 15, 1930).

FRENCH LICK PURE TOMATO JUICE

Manufacturer.—Tomato Products Company, Paoli, Ind.

Description.—Canned or bottled tomato juice retaining in high degree the vitamin content of the raw juice; seasoned with salt.

Manufacture.—Tomatoes are placed in a tank of water to loosen field dirt, are thoroughly washed by high pressure water sprays and are inspected on sorting tables; sound ripe tomatoes, trimmed of green portions if necessary, are selected for the tomato juice and transferred to the pressing apparatus, a cylindric screen with paddles, which rub the fruit against the screen. Live steam surrounds the apparatus and prevents the inclusion of air. The juice from the first screen is passed through a much finer screen to reduce the size of the particles and eliminate any coarse fibrous material. The juice is drawn through a continuous deaerating apparatus by means of reduced pressure in which it is sprayed into a "high vacuum" chamber, thus eliminating most of the dissolved or incorporated air. It is transferred to storage tanks through the bottom to avoid splashing and inclusion of air. A small amount of salt is added, and each batch is brought to a temperature of 71 C. as rapidly as possible. It is filled into bottles or cans, hermetically sealed, processed in hot water (No. 1 tins for twenty minutes at 93 C.), and immediately cooled.

Analysis (submitted by manufacturer).—

	per cent
Moisture	94.4
Total solids	5.6
Ash	0.7
Salt	0.3
Fat	0.0
Protein (N × 6.25)	1.2
Crude fiber	0.4
Carbohydrates other than crude fiber (by difference)	3.3

Calories.—0.2 per gram; 6 per ounce.

Vitamins.—The use of mature tomatoes, the careful factory control, the continuous method of manufacture, the exposure of the fruit juice to an atmosphere of steam only in the factory equipment, and the withdrawal in the "vacuum" treatment of air naturally occurring in the juice assure maximum retention of the natural vitamin content.

Claims of Manufacturer.—This tomato juice is a good source of vitamins A and B and an excellent source of vitamin C. It is recommended for general table use and as an accessory vitamin C food for infant feeding.

N. J. C. BRAND PANCAKE SYRUP

(85 Per Cent Corn Syrup, 15 Per Cent Refiners' Syrup)

Packer.—D. B. Scully Syrup Company, Chicago.

Distributor.—Northern Jobbing Company, Chicago and St. Paul.

Description.—A table syrup; a corn syrup flavored with refiners' syrup.

Manufacture, Analysis, Calories, Claims of Manufacturer.—See these sections for Banner Blue Corn Syrup with Cane Flavor (THE JOURNAL, March 5, 1932, p. 817).

HIRES ROOT BEER

(Concentrated Extract and Flavoring for Preparation of "Root Beer")

Manufacturer.—Charles E. Hires Company, Philadelphia.

Description.—A water solution or suspension of caramel and aqueous extracts of sassafras, sarsaparilla, licorice and ginger roots, juniper berries, dog grass, birch bark, hops, spikenard and pipsissewa herbs, vanilla beans and wintergreen and deer tongue leaves; for the preparation of "root beer" and fountain syrup beverages.

Manufacture.—The raw materials from various countries are ground in a root mill and extracted with a solution of water and alcohol. The alcohol is distilled off; the resulting aqueous extract is diluted with water to precipitate out some of the gums and resinous matter that would interfere with the preparation of a clear beverage. Caramel is added and the final mixture packed in containers.

Analysis (submitted by manufacturer).—

	per cent
Total solids	30.9
Ash	0.7
Nitrogen	0.1
Volatile oils	0.9
Sucrose	0.0
Reducing sugars, before inversion as dextrose	5.9
Reducing sugars, after inversion as dextrose	5.9
Non-sugar solids (caramel and organic plant extractives)	24.3
Alcohol	absent
Alkaloids	absent
Saponin	absent
Coal tar color	absent

Claims of Manufacturer.—A concentrated extract for the preparation of the table beverage "root beer."

HUMMER HIGHEST PATENT FLOUR
MENU HIGHEST PATENT FLOUR

Manufacturer.—Slater Mill & Elevator Company, Slater, Mo.

Description.—An "all purpose" short patent flour prepared from soft red wheat; bleached.

Manufacture.—Selected soft red wheat is cleaned, scoured, tempered and milled by essentially the same procedures as described in THE JOURNAL, June 18, 1932, page 2210. Chosen flour streams are blended, bleached with one-eighth ounce mix of benzoyl peroxide and calcium phosphate and one-fourth ounce of chlorine per barrel, and automatically packed in cotton and paper sacks.

Analysis (submitted by manufacturer).—

	per cent
Moisture	10.4
Ash	0.33
Fat (ether extraction method)	0.8
Protein (N × 5.7)	9.5
Crude fiber	0.5
Carbohydrates other than crude fiber (by difference)	78.5

Calories.—3.6 per gram; 102 per ounce.

Claims of Manufacturer.—An "all purpose" short patent flour for general baking uses.

TEETH AND THE DIET

Within the last few years, considerable experimental data have accumulated showing that dental caries can be prevented or controlled by eating the proper foods. Among the more extensive reports may be mentioned [1] those of Bunting and his collaborators at Ann Arbor, Mellanby in England, Boyd, Drain and Nelson in Iowa City, and Hanke in Chicago. Taken collectively, these experiments demonstrate that dental caries may be considered largely as a dietary deficiency disease, a statistical fact of peculiar significance because of the amenability of this class of disorders to treatment. More striking, perhaps, is the insinuation that the complacent attitude of many persons relative to the supposed adequacy of the "average" American diet may be wholly unfounded. In a brief report of the incidence of caries in 1,192 children in public schools and orphanages in Michigan, tooth decay has been found by Bunting, Jay and Hard [2] in from 80 to 99 per cent of the children in the various groups that were studied. Active caries was noted in from 72 to 90 per cent of the public school children examined again at the end of a year, the number of teeth affected averaging from three to four for each child. There is reason to believe that the status of the teeth in Michigan children is not unique but could be duplicated in most other communities in this country. From the standpoint of the dietary requirements for good tooth formation and preservation, it would seem that the food we eat may not be wisely selected.

Although the importance of nutrition in dental and oral hygiene has been established, a recent commentator [1] has pointed out the wide existing differences of opinion regarding the particular dietary principle or group of factors responsible for the beneficial results. Some investigators have emphasized the rôle of vitamin C, pointing to the response of the teeth and gums in experimental scurvy. Others, reasoning that the metabolism of the teeth, like that of the bones, is governed by vitamin D, consider the antirachitic factor as the responsible agent. There is experimental evidence to support each assumption. Hess and Abramson,[3] however, have pointed out that poor teeth are prevalent in geographic situations where the diet is such that it precludes the possibility of deficient intakes of vitamins C or D.

Other hypotheses have sought to correlate bad teeth with the consumption of excessive amounts of sugar, with the ingestion of foods that have a potentially acid ash, and with various phenomena not directly dependent on the diet. Klein and McCollum [4] suggest that the ratio of dietary calcium to phosphorus is important, caries in rats occurring when there is a relative deficiency of phosphorus. Their results promise to explain some of the anomalies now present in the literature.

To formulate actual menus with something more than rule of thumb as a guide or to provide substitute foods when certain recommended articles are economically, geographically, seasonally or otherwise unobtainable will require a knowledge of the chemical ingredients of the diet that are necessary to insure good teeth. Such specific information has not as yet been acquired. Adequately controlled tests on human subjects cannot be done readily, and the interpretation of the work accomplished at present is difficult. Recourse to animal feeding experiments, a method employed with signal success in the elucidation of nearly all the dietary deficiency diseases so far investigated, is beset with unusual difficulties when applied to the study of the effect of diet on the teeth. As is well known, the prominent incisors of rodents grow from persistent pulps, and other teeth likewise may not be precisely analogous to either the deciduous or the permanent teeth of man. In addition to the structural differences there are a number of metabolic variations between species that limit experimental procedure. The rat thrives on diets devoid of vitamin C, and the guinea-pig, although susceptible to scurvy, is resistant to a deficiency of the antirachitic factor. Because of such handicaps, extreme caution must be applied before experimental results with animals can be interpreted in terms of human experience.

The results of studies of children, however, are at least unanimous in showing that efforts to provide an improved diet are in the main rewarded with increased resistance to tooth decay. This in itself is cause for gratification and should be an incentive to further study. Whether the prophylactic substance is one of the vitamins or some other factor, either known or as yet unrecognized, or even a combination of these in optimal amounts, must await future research.

THE RELATIVE EFFICIENCY OF VITAMIN D PREPARATIONS IN DIFFERENT SPECIES

The discovery of the antirachitic potency of viosterol (irradiated ergosterol) created the hope that the strength of each of the many specifics for the treatment of rickets could be simply expressed in terms of a pure chemical substance. As is well known, the question of the proper dosage of viosterol led to the present knowledge of the exceedingly small amounts effective in the prevention or cure of rickets, and the hypercalcemia, pathologic calcification of the blood vessels and soft tissues, and other symptoms constituting the picture of hypervitaminosis due to enormous overdosage of this substance.[1] But the variations in potency of different preparations, coupled with the previous lack of information regarding the chemical structure of vitamin D, led in this country and elsewhere to the abandonment of gravimetric units and the substitution of direct biologic assay in which the strength of each preparation is expressed in terms of rat units per gram. Clinical experience soon revealed that various products of equivalent antirachitic potency, as judged by the rat test, possessed markedly different values for the treatment of infants. Some time ago, Hess[2] reported that a viosterol preparation, equivalent to approximately ten teaspoonfuls of cod liver oil, did not suffice to prevent typical roentgenologic signs of rickets in children. While the infant requires only twenty times as much cod liver oil as the rat, on the basis of equal weights, about sixty times as much viosterol is necessary. There is some evidence indicating that irradiated milk, or milk from cows fed irradiated yeast, is somewhat more efficient in the child than in the rat, when cod liver oil is the basis of comparison. To protect the average child from rickets, Hess and his collaborators find that about one liter of suitably activated milk, 15 cc. of standard cod liver oil, or ten drops of viosterol is sufficient. In terms of rat units these quantities are respectively 160, 200 and 830; that is, for each rat unit in the form of activated milk, 1.25 units as cod liver oil or 5.2 units as viosterol is required. These variations are accentuated when, instead of the infant, the response of the fowl is studied.

Such differences in effectiveness of the antirachitic factor in various species may be due to inherent difficulties in the biologic method of assay, to the widely differing types of food ingested by various species, to altered utilization of the vitamins because of possible variations in absorption, or, perhaps, to variations in the pathogenesis of rickets in different species. Regardless of the causes, these differences can readily be compensated for by altering the dosage in accordance with experimental facts. The differences in pharmacologic activity, therefore, should not be construed as evidence purporting to discount the value of viosterol.

Confirming and amplifying previous reports, the recent experiments of Steenbock, Kletzien and Halpin,[3] on the relative antirachitic potency of various vitamin D preparations for chickens, offer a new interpretation for these phenomena. When 1 per cent of cod liver oil, of standard strength, was incorporated in a rachitogenic diet, rickets was prevented. In comparison, protection was also afforded by from 7.5 to 60 times as many rat units in the form of irradiated yeast, and by 40 to 120 times, as irradiated ergosterol. Burbot liver oil, however, had the same value as cod liver oil in both rats and chickens. Further experiments were performed to test the hypothesis that some substance in fish liver oils might increase the efficiency with which vitamin D functions. Excessive amounts of irradiated ergosterol, whether dissolved in cod liver oil or corn oil, produced about the same degree of hypervitaminosis; hence the toxic effects of the antirachitic factor were not affected by the nature of the solvent. Therapeutic doses gave similar results, although the amount of cod liver oil in which the ergosterol could be dissolved was necessarily limited. The liver oil, fortified so that 0.1 or 0.05 per cent of the diet had the equivalent in rat units of 1 per cent cod liver oil, produced no increased deposition of bone ash above that observed in rachitic birds. The Wisconsin investigators[3] therefore conclude that the vitamin D produced by ordinary irradiation of ergosterol with a quartz mercury lamp is a different substance from that found in cod liver oil. It will be recalled, in this connection, that it was observed[4] in 1929 that provitamin D activity is not necessarily limited to ergosterol but may be a general property in varying degrees of different sterols.

In view of the studies of the relative values of irradiated products as compared with cod liver oil in different species, it would be interesting to know the efficiency of direct irradiation in the same animals. Although the presence of a skin protected by fur or feathers, as well as other considerations, offers experimental difficulties to the securing of quantitative data, it is known that such therapy is effective in all species. Pediatricians on more than one occasion have noted the effectiveness of direct irradiation of infants as contrasted with the occasional appearance of craniotabes and other signs of mild rickets in infants supposedly protected by adequate doses of cod liver oil or viosterol. So striking are these and other discrepancies that some clinicians go so far as to consider the antirachitic factor as something distinct from a vitamin or similar food constituent. Further study of the problem along the lines suggested by the concept of multiple vitamin D paring a wild rabbit for cooking The husband developed the oculoglandular form of the disease, the wife became ill at approximately the same time with ulceroglandular tularemia The specific agglutination tests were strongly positive in both instances Two other cases of ulceroglandular tularemia have been encountered at the same clinic Granstrom directs particular attention to the close similarity of the symptoms and signs of Parinaud's disease and oculoglandular tularemia He states that many cases which had been diagnosed as Parinaud's disease were later proved to be cases of "conjunctivitis tularensis"

Association News

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts on Monday and Wednesday from 10 45 to 10 50 a m over Station WBBM (770 kilocycles, or 389 4 meters) The Columbia chain program has been discontinued for the present

The subjects for the week are as follows

August 15 Bootleg Milk
August 17 School Days Are Here Again

There is also a fifteen minute talk sponsored by the Association on Saturday morning from 10 45 to 11 over Station WBBM

The subject for the week is as follows

August 20 Vacation Health

This schedule is based on Chicago Daylight Saving Time, one hour faster than Central Standard Time

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest such as relate to society activities, new hospitals, education public health, etc)

ARIZONA

Society News—Officers elected at the recent annual session of the Arizona Public Health Association are president Dr Alvy N Crain, director, Maricopa County health unit, vice presidents, W J Jamieson, city engineer of Phoenix, and Dr Raphael B Durfee, county health officer, Bisbee, and secretary, Jane H Rider, director, state laboratory, Tucson Dr Charles E Irvin, Miami presided as toastmaster at the dinner, and Dr Fred T. Foard, U S Public Health Service, spoke

CALIFORNIA

Society News—The San Francisco County Medical Society was addressed, August 9, among others, by Drs Norman N Epstein and Sarkis B Paul, San Francisco, 'Treatment of Syphilis by Means of Hyperpyrexia Produced by Diathermy "——Dr Camille Kereszturi, New York gave an illustrated address on "The Use of B C G Vaccine" before the Trudeau Society, Los Angeles, August 2

Clams Now Poisonous.—Recent laboratory examinations disclosed that all clams, with the exception of mudclams, as well as mussels from certain sections along the coast of California are now poisonous The state department of health has therefore established a quarantine, prohibiting the sale or offering for sale of all clams, with the exception of mudclams, in the coastal area from Monterey County to the Klamath River in Del Norte County, excluding San Francisco Bay This quarantine will be in effect until September 30 Mussels and clams in the San Francisco Bay waters do not show signs of toxicity, as do shellfish in ocean waters However, the bulletin of the state board reports, this action does not affect a permanent quarantine on clams in San Francisco Bay, which was established, May 28, because of sewage pollution of the bay waters The order also includes mudclams

COLORADO

Society News.—Dr Harold B Henderson, Denver, addressed the Larimer County Medical Society, July 6, on 'Practical Points in Gynecology "——At the meeting of the Otero County Medical Society in Rocky Ford, July 14, Dr Elmer L Timmons, Colorado Springs, talked on pediatrics, and Dr William P McCrossin, Jr, Colorado Springs, cervicitis, including etiology, diagnosis and treatment

State Medical Meeting at Estes Park.—The sixty-second annual session of the Colorado State Medical Society will be held at the Stanley Hotel, Estes Park, September 8-10, under the presidency of Dr Edward Delehanty, Denver Guest speakers included on the scientific program are Drs Theodore H Weisenburg, professor of neurology, Graduate School of Medicine, University of Pennsylvania, "Recent Advances in the Commoner Nervous Diseases', Edward H Skinner, Kansas City, "Relation of Roentgenology to Other Fields of Medical Practice', Isaac A Abt, professor of pediatrics, Northwestern University Medical School, Chicago, "Pneumonia in Childhood" and Frank D Dickson, Kansas City, "Low Back Injuries with Particular Reference to the Part Played by Congenital Abnormalities" Among other Colorado physicians participating in the program will be Drs Maurice Rees, dean, University of Colorado School of Medicine, Denver, "Recent Progress in Medicine', Carl W Maynard, Pueblo, "Cholecystectomy and Its Surgical Pathology', Clyde T Knuckey, Lamar, 'Obstetrics from the Standpoint of the General Practitioner,' and Marcus O Shivers, Colorado Springs, "Means and Methods of Goiter Prophylaxis' Dr Edward H Cary, Dallas, Texas, President, American Medical Association, will deliver an address at the annual banquet In addition to the golf tournament, a program of entertainment has been arranged

GEORGIA

Society News—Dr John L Elliott, Savannah, addressed the Georgia Medical Society, June 14, on "Hyperemesis Gravidarum'——The Ocmulgee Medical Society was addressed at Hawkinsville June 17, by Drs Wallace L Bazemore and Charles H Richardson Jr, Macon on transurethral prostatic resection and acute conditions in the abdomen, respectively ——At a meeting of the Randolph County Medical Society in Cuthbert July 7, Dr Clarence R Bennett, Eufaula Ala spoke on 'Aortitis and Aortic Insufficiency'——The Thomas County Medical Society was addressed in Thomasville, June 22, by Drs Simeon E Sanchez Barwick, on 'Anemia in Pregnancy,' and Charles H Watt Thomasville, "Acute Osteomyelitis ——The Sixth District Medical Society was addressed June 29, at Indian Springs among others, by Drs Bernard McH Cline, Atlanta, on 'Peroral Endoscopy in Relation to General Medicine and Ernest Corn, Macon, Transurethral Resection of the Prostate'——Dr Evert A Bancker Jr Atlanta read a paper on Coronary Disease before the Fulton County Medical Society August 4 Dr Bernard L Shackleford gave a clinical talk on "Reflex Conditions"

ILLINOIS

Health Exhibit at State Fair—Plans have been completed by the state department of public health for displaying at the Illinois State Fair in Springfield, August 20 27, the most extensive and comprehensive health and sanitary exhibit ever presented in connection with the event, the *Illinois Health Messenger* reports The displays relate to milk, water, diet, laboratory procedures insect pests personal hygiene and various specific diseases such as smallpox typhoid, cancer, heart disease pneumonia tuberculosis, diphtheria, scarlet fever and rabies A baby conference which is undertaken as a demonstration, it was stated, will be held in connection with the exhibit Children from 6 months to 10 years of age are eligible for registration and examination

One Case of Diphtheria in Twelve Years—At the Mooseheart School, Mooseheart, which has an enrolment of about 1,500, there has occurred only one case of diphtheria since 1920, and not a case of scarlet fever since 1926, among the tested and immunized students There have been no cases of diphtheria at the Soldiers Orphans Home, Normal, which has a constant child population of more than 650, and none of scarlet fever since October of 1929 One case was reported in that year Immunization work started at the home in 1925, and at Mooseheart in 1926. All children present at that time were given the Dick test and treated with the Dick scarlet fever toxin. Since that time all children admitted to the orphans' home have been tested at the time of admission and the reactors immunized. At Mooseheart the testing is done each six months, those previously immunized being retested along with those newly admitted. Drs. Ralph P. Peairs and John D. Nichols are the medical directors, respectively, of the home and of Mooseheart School.

INDIANA

Personal.—Dr. Frank V. Newcomer has been appointed a member of the city board of health to succeed the late Dr. Edward M. Boggess, Elwood. Dr. Newcomer is president of the Elwood Medical Society.——Dr. Thomas J. McKean, Montpelier, was appointed health officer of Montpelier recently to succeed the late Dr. Marion A. Emshwiller.——Dr. Leonard A. Ensminger has been appointed chairman of the department of orthopedic surgery of Indiana University School of Medicine, Indianapolis, and Dr. Raymond C. Beeler has been appointed chairman of the division of radiology, department of surgery. ——Dr. Thurman B. Rice, Indianapolis, addressed the Parke-Vermillion Counties Medical Society, June 22, on "Newer Concepts of Bacteriology."

IOWA

Society News.—The Iowa and Illinois Central Medical Association, at its annual meeting in Davenport, July 14, elected the following officers: Drs. Hugh A. Beam, Moline, president; Harry H. Lamb, Davenport, vice president; Karl W. Wahlberg, Moline, secretary, and John H. Fowler, East Moline, treasurer. Dr. E. Starr Judd, Rochester, Minn., formerly President, American Medical Association, spoke on "Surgery of the Biliary Tract." Other speakers were Drs. John F. Ritter, Maquoketa, on "Nascent Endocrine Therapy"; John H. Peck, Des Moines, "Childhood Tuberculosis," and Fred M. Smith, Iowa City, "Discussion of Certain Aspects in the Treatment of Cardiac Failure." Dr. George Braunlich, Davenport, retiring president, gave his official address.

KENTUCKY

Health Material Available in Libraries.—The state board of health, through its social hygiene division, is asking the cooperation of free public libraries in Kentucky in making available to parents, teachers and others interested in the proper training of children, authoritative material on training for parenthood, character development and child guidance. It is planned to donate about ten new books, from a selected list, to any public library that will definitely establish a social hygiene section and assist in getting these books circulated. The social hygiene division, which is known as the Social Hygiene Association of Kentucky, hopes in this way to form a nucleus which will be augmented from time to time by the library boards as public demand warrants. Included in this offer is a complete set of social hygiene pamphlets for use in the reading rooms. It was stated that fourteen of the seventy public libraries in the state are now so equipped.

MAINE

Society News.—The Hancock County Medical Society was addressed at Bar Harbor, July 20, by Drs. Edward H. Risley, Waterville, "Treatment of Head Injuries," and Francis T. Hunter, Boston, "Modern Treatment of Diseases of the Blood." ——At a meeting of the Somerset County Medical Society at Lake Wesserunsett, June 30, Drs. Elmer D. Merrill, Dover-Foxcroft, and Warren E. Kershner, Bath, president and president-elect, respectively, of the Maine Medical Association, spoke. Dr. Merrill discussed cults from a legislative standpoint, and Dr. Kershner, medical organization. Dr. George R. R. Hertzberg, Stamford, Conn., read a paper on the use of camphor oil as an antiseptic in first aid dressings and in the treatment of burns, ulcers, bed sores and like conditions.

MARYLAND

In Memoriam.—The *Bulletin* of the University of Maryland School of Medicine dedicated its July issue to the memory of Dr. C. Hampson Jones, late professor of hygiene and public health at the school, and commissioner of health of Baltimore.

Increase in Venereal Disease.—An increase of more than 7,000 treatments for venereal disease was noted during the first six months of this year in Baltimore dispensaries, as compared with the number given during the corresponding period of last year, the city department of communicable disease reports. During the month of June, 157 more patients were reported than for the same month last year. In one dispensary, 217 women were treated on one clinic night and 150 in the afternoon of the same day. The current economic condition may be charged with this increase, it was said, because patients in better times would probably go to private physicians for treatment. These dispensaries in the city are manned by six Negro and four white physicians. It is expected that at the present rate of increase it will be necessary for the city clinics to give more than 80,000 treatments by the end of this year, and should conditions not improve these figures will increase to more than 110,000 by the end of 1933. A survey made by the public health service in 1931 showed that more than 10,000 active cases of gonorrhea and syphilis are constantly under treatment in Baltimore, with more than 10,000 new infections each year. The rate among the Negro population is about four times as high as among the white population.

MINNESOTA

Short Courses on Tuberculosis.—July 17 marked the opening this year of the short courses on tuberculosis given throughout the state, through the cooperation of the sanatoriums and the Minnesota Public Health Association. The first course was held at the Otter Tail County Sanatorium at Battle Lake. The second one will be held, August 31, at Buena Vista Sanatorium, Wabasha. Speakers on the program will be Drs. Jay Arthur Myers, Minneapolis; Francis F. Callahan, Pokegama; Walter H. Ude, Minneapolis; Charles N. Hensel, St. Paul; Russell H. Frost, Wabasha, and Edward A. Meyerding, St. Paul. Every physician will be given an opportunity to make examination and diagnosis of several patients under the direct supervision of one of the tuberculosis specialists. Enrolment is limited to twenty-five.

Society Holds Sixty-Fourth Annual Meeting.—Wabasha County Medical Society held its sixty-fourth annual meeting at Plainview, July 7. Dr. William B. Stryker, Plainview, was elected president; Dr. Rudolph C. Radabaugh, Hastings, vice president, and Dr. William F. Wilson, Lake City, secretary. The retiring president, Dr. William F. Wilson, Lake City, spoke on "Some Changes in Thirty-Eight Years"; Dr. George B. Eusterman, Rochester, Minn., "New Developments in the Diagnosis and Treatment of Gastric Cancer and Ulcer"; Dr. Radabaugh, "Osteomyelitis of Humerus Treated with Maggots"; Dr. David G. Gardiner, St. Paul, "Peroral Endoscopy," and Dr. Thomas Myers, St. Paul, "Simplified Infant Feeding." The next annual meeting will be held in Wabasha in July, 1933. A resolution was adopted at the recent meeting providing for reciprocal relations between the Winona and Wabasha county medical societies, and calling for one or more joint scientific and social meetings to be held during the year, alternately in each county.

MISSOURI

Society News.—Dr. George Leonard Harrington, Kansas City, addressed the Jasper County Medical Association in Joplin, June 7, on "Mental Health and Depression."——Dr. Eugene M. Lucke, health officer of Marion County, Hannibal, was elected president of the Missouri Public Health Association, June 10.

Appointments at St. Louis University.—Announcement has been made of the following appointments and promotions in St. Louis University School of Medicine, among others:

PROMOTIONS

Alrick B. Hertzman, Ph.D., associate professor of physiology.
Dr. Florent E. Franke, assistant professor of physiology.
Dr. Alver H. Kerper, assistant professor of anatomy.
Dr. John Anthony Brennan, instructor in internal medicine.
Dr. John J. Hammond, instructor in internal medicine.
Dr. Daniel L. Sexton, instructor in internal medicine.
Dr. Emanuel Sigoloff, instructor in internal medicine.
Dr. Neil S. Moore, instructor in urology.
Dr. George H. Koenig, instructor in urology.
Dr. Carl F. Vohs, instructor in orthopedic surgery.

APPOINTMENTS

Dr. John H. Hershey, assistant in anatomy.
Dr. Raymond O. Muether, assistant in internal medicine.
Dr. James H. Ready, assistant in internal medicine.
Dr. Carl J. Reis, assistant in internal medicine.
Dr. Jerome Diamond, assistant in pediatrics.
Dr. Howard L. Lange, assistant in pediatrics.
Dr. Samuel J. Freund, assistant in surgery.
Dr. Thomas E. McGurk, assistant in surgery.

Dr. Joseph Mülzer of the University of Heidelberg was designated to receive the Carl Barck fellowship in ophthalmology, established a year ago, newspapers state, when the University of Freiburg conferred a golden doctorate on

Dr Barck in appreciation of his fifty years' service in ophthalmology Dr Mulzer will have special research duties in the new Firmin Desloge Hospital Dr Goronwy O. Broun was appointed director of the university hospitals.

NEBRASKA

Hospital News.—The Douglas County Hospital, Omaha, a new institution with 135 beds for tuberculosis and 85 for nervous and mental diseases, was dedicated, June 27 The five-story building was constructed at a cost of about $900,000

Personal.—Dr Otis Merriam Cope, associate professor of physiology and pharmacology in the University of Nebraska School of Medicine, Omaha, has resigned to become professor of physiologic chemistry at the New York Homeopathic Medical College

Society News.—The first scientific meeting of the Southwest Nebraska Medical Society was held in McCook, June 9 Three Omaha physicians made addresses as follows Charles A Owens, Jr, on "Diagnosis of Prostatic Disease", Arthur D Dunn, "Relationship of Paranasal Sinusitis to Systemic Disease," and Herbert H Davis, "Tumors of the Breast"——Dr Ora S Fowler, Denver, addressed the Scotts Bluff County Medical Society, Scottsbluff, June 16, on visceroptosis and nephropexy ——The Northeast Nebraska Five-County Medical Society joined the Madison Six-County society in its June meeting in Norfolk Speakers were Drs Bennie R Farner, Norfolk, on "Accidental Tissue Transplantations", Harry L Harvey, Lincoln, "Recent Developments of Endocrinology as Related to Gynecology," and Arthur E Hertzler, Halstead, Kan, clinical methods of diagnosis and treatment——A Sixth Councilor District Medical Society was organized at Stromsburg, June 27, with Dr Dexter D King, York, as president

NEW JERSEY

Trachoma in Orphanage.—Eighty-two cases of trachoma had been discovered in the state up to the middle of June in the course of an investigation begun after a number of cases were discovered in an orphanage in Mercer County in May The average annual number of cases of trachoma in New Jersey in the last five years was only seventeen The fact that the disease had probably existed in the orphanage for at least two years and that boys had been placed in families throughout the state added to the difficulty of the investigation which has been carried on by the state and local boards of health and the state board of children's guardians

Outbreak of Undulant Fever—Twelve cases of undulant fever were traced to a single herd of cattle, from which milk was sold to nine communities during the summer and fall of 1931, according to an epidemiologic report in *Public Health News* The dealer who sold the milk maintained a herd of high grade cows on his country estate and raw milk was sold at higher prices than those charged by other dealers Investigation revealed that this herd had been affected with contagious abortion at various times between June 1926, and May, 1931, and that several reactors had been slaughtered Eleven of the patients were infected through the use of raw milk or cream from this dairy, and the twelfth case occurred in a veterinarian employed for the infected herd of cattle The dealer installed a pasteurizer at the time the investigation was begun, Oct 28, 1931 When it was finally established that his product was the source of the cases investigated the state board of health served an order on him prohibiting the sale of raw milk or cream produced or stored in his dairy until the herd was proved to be free from contagious abortion Two other cases are included in the report but it was established that these originated outside the communities in which they were diagnosed

NEW YORK

Lake Keuka Medical Meeting.—The thirty third annual meeting of the Lake Keuka Medical and Surgical Association was held at Lake Keuka Hotel, July 14-15 The program included the following speakers Drs Frederick S Wetherell, Syracuse, "Spinal Anesthesia in Surgery', Max M Peet, Ann Arbor, 'Head Injuries" Foster Kennedy, New York, "Neuroses Following Accidents', George B Magrath, Boston, "Medical Science in the Service of the State with Special Reference to Investigation of Deaths', Howard M Clute, Boston "Diagnosis and Management of Obstructive Jaundice , Descum C McKenney, Buffalo, 'Blood in Stools of Colonic Origin", William L Wallace, Syracuse, "Avertin in Surgery" Dr Harold O Jones, Chicago, showed a sound film on 'Repair of Second and Third Degree Lacerations of the Perineum and Rectocele" Dr. Frederick H Flaherty, Syracuse, president-elect of the New York State Medical Society, made the opening address on medical organization

New York City

Hospital Allowance for Care of Indigents—The United Hospital Fund, representing fifty-six private hospitals in New York, has appealed to the Board of Estimate and Apportionment to increase the allowance for care of patients recognized as public charges from $3 to $4 50 It was pointed out that the amount allowed was about half the cost of their treatment and also that the number of such patients had doubled in the last five years The statement declared that the hospitals would not be able to meet what promises to be a greater demand than ever during the coming winter unless early and substantial help came from the city In 1931, it was said, forty-three general and special hospitals and branches gave 788,062 days of hospital care to indigent patients in addition to their service to free and part-free patients for whom the city paid nothing

Outbreak of Wood Alcohol Poisoning.—Eighteen men died of wood alcohol poisoning in the lower East Side district between July 27 and 31, according to newspaper reports Seven were found dead in parks or on the streets and the remainder died within an hour after being taken to Bellevue and Broad Street hospitals from various places from the Bowery to the Battery Alexander O Gettler, Ph D, city toxicologist, and Dr Harry Schwartz, assistant medical examiner, made the chemical analysis that determined the cause of death First-hand information as to the source of the poison liquor could not be obtained, as all the victims who were still alive when found were unconscious, but Dr Charles Norris, chief medical examiner, expressed the belief that it had all come from a common source It was said that the last outbreak of the kind occurred in 1930, when thirty died during the month of June.

NORTH CAROLINA

Hospital News.—A new hospital, known as the Lyday Memorial Hospital, was opened, June 6, in Brevard——The new $130,000 unit of the Randolph Hospital, Asheboro, was recently opened, it is reported The cost was financed in part by the Duke Endowment

Society News—Dr William A Frontz, Baltimore, recently addressed the Guilford County Medical Society on "Malignant Disease of the Prostate and Bladder' Dr Frontz addressed the Buncombe County Medical Society, June 20 on hematuria, with special reference to early diagnosis——Drs James W Gibbon and Oscar L Miller addressed the Mecklenburg County Medical Society, Charlotte, June 7, on "Surgery of the Large Intestine and 'Treatment of Tuberculous Hips in Children by Surgical Fusion respectively——Drs Richard B Davis and Charles A Julian both of Greensboro, were speakers before the Robeson County Medical Society, June 18 on 'The Logical Incision for an Appendectomy" and "Nervous Indigestion, respectively

PENNSYLVANIA

Society News—The Fayette County Medical Society held a clinical meeting, August 4 at Uniontown, with Drs Alexander M Duff, Jr, Republic, and William A McHugh, Jr, Uniontown among others, as speakers, on "Public Health Aspects of Rabies and Neurofibromatosis of the Peritoneum," respectively——Dr Jonathan M Wainwright, Scranton, was elected president of the Lehigh Valley Medical Association at the fifty-second annual session at Pocono Manor, July 21. Speakers at the meeting were Drs William J Schatz, Allentown, on "Evolution of the Present-Day Saline Solution"; Samuel B English Glen Gardner, N J, 'Fifty Years' Progress in Medicine," and Edward J G Beardsley, Philadelphia, 'Role of Physical Examination in Diagnosis"

Philadelphia

Diphtheria Campaign—Temporary clinics established for intensive immunization in the city's fifth annual campaign against diphtheria, June 6-24, treated 9,851 children Each child that received three injections was furnished with a certificate stating the approximate date of the injections, and advising the parent to bring the child back at the end of six months to determine the effect of immunization If the child is then found immune, he will be given a certificate stating this fact The campaign was carried on in sixty-six public schools, eighteen parochial schools and ten health centers

SOUTH DAKOTA

Society News. — Dr. Solon Marx White, Minneapolis, addressed the Sioux Falls District Medical Society, June 14, on heart disease in pregnancy.——Dr. Daniel S. Baughman addressed the Third District Medical Society at Madison, June 3, on "Tumors of the Testicle."——A $375,000 sanatorium for Indians with tuberculosis will be started at once at Fort Pierre, it is reported.

TEXAS

University News.—Dr. John O. McReynolds, Dallas, has presented to the University of Texas School of Medicine a scientific exhibit relating to the crystalline lens system in man and the lower animals. The collection assembled by Dr. McReynolds consists of photographs and mounted lenses of the various species of the animal kingdom, and 300 cataract lenses removed in the capsule, together with slides illustrating the pathologic processes and the embryology of lenses.

Society News. — Dr. Henry F. Carman, Dallas, among others, addressed the Tarrant County Medical Society, Fort Worth, June 7, on artificial pneumothorax.——Physicians of Jim Wells, Brooks and Duval counties organized a tricounty medical society, June 7, with Dr. John S. Strickland, Alice, as president and Dr. George G. Wyche, Alice, secretary.——Among speakers at the semiannual meeting of the North Texas District Medical Society at Bonham, June 14-15, were Drs. Alfred I. Folsom, Dallas, on "Prostatic Resection"; Lois Weir Smith, Sherman, "Fermentation Diarrhea in Infancy"; Everett C. Fox, Dallas, "Precancerous Dermatoses," and Daniel B. Westerman, Cooper, "Peptic Ulcer of Stomach and Duodenum."——Dr. Charles P. Coogle of the U. S. Public Health Service, Longview, among others, addressed the Van Zandt County Medical Society, June 3, on malaria control.——A program of lectures on cancer was presented at Sherman, June 7, under the auspices of the Grayson County Medical Society, by Drs. Arthur C. Scott of Temple and John L. Goforth and Curtice Rosser, both of Dallas.

GENERAL

News of Epidemics.—Quarantine was suddenly imposed on a national guard encampment at Camp Perry, Ohio, July 10, when thirty cases of chickenpox were discovered among the 2,700 officers and enlisted men in training there.——Fourteen cases of scarlet fever in a residential section of Elizabeth, N. J., between June 13 and 18, were traced to the use of raw milk from a single dealer. Infection was believed to have come from two cases of the disease in the dealer's family. It was said that the dealer involved had been a strenuous objector to a proposed ordinance requiring pasteurization of milk; he had, however, arranged to pasteurize his supply after the outbreak of scarlet fever.——General vaccination against smallpox was ordered by the mayor of Niles Center, Ill., July 20, after several cases were discovered in the village.

Society News.—All the officers were reelected at the seventeenth annual convention of the Catholic Hospital Association of the United States and Canada held, June 21-24, at Villanova College, Villanova, Pa. The program included the following speakers: Dr. Edward H. Cary, Dallas, President, American Medical Association, in "Federal and State Hospital Legislation"; E. H. Lewinski-Corwin, Ph.D., New York, "Nomenclature of Diseases and Operations"; James B. Hagerty, D.D.S., "Dental Service in the Hospital in Relation to Medical Care"; Dr. Michael O. Cunningham, Deming, N. M., "Requirements for the Care of the Tuberculous Patient"; Mr. Homer F. Sanger, Chicago, "National Hospital Development," and Dr. James P. Dean, Madison, Wis., "Essential Factors of a Diagnostic Service." The meeting was conducted with the Rev. Alphonse M. Schwitalla, St. Louis, presiding.——The fourth annual meeting of the Aero Medical Association will be held in Cleveland, September 3-5, under the presidency of Dr. Ralph N. Greene, Jacksonville, Fla. The association is made up of medical examiners of the aeronautics branch of the U. S. Department of Commerce, and army and navy flight surgeons. Dr. William B. Smith, Hartford, Conn., is the secretary. Among speakers will be Major Eugene J. G. Reinartz, Medical Corps, U. S. Army, on "Neuropsychiatric Problems of a Flight Surgeon," and Herbert B. Wright, Cleveland, "Medical Supervision."

Traffic Deaths Rise to 30,000.—An increase was noted in the mortality from automobile accidents in 1931, as compared with the total for the year 1930. The U. S. Department of Commerce, in its provisional summary for 1931, announces that during the calendar year in the death registration area of continental United States, exclusive of Utah, there were 29,547 deaths from these accidents, not including collisions of automobiles with railroad trains and street cars. In 1930, in the same area, there were 28,950 deaths from this cause. The death rates were 24.9 and 24.5 for the respective years. In these two years, forty-seven states, the District of Columbia, and eight registration cities in the nonregistration state of Texas composed the area in continental United States, or 95.7 per cent of the total population. Considering the states by geographic divisions, the Pacific group had the highest death rate (34.6 per hundred thousand of population) in both years. Nevada, with a rate of 68.5, had the highest rate for states when considered separately. The rate for Nevada almost doubled, the rate in 1930 being 37.4. Mississippi had the lowest mortality rate (14). The city having the highest mortality rate from this cause was Camden (84). The total number of deaths within a city should not be taken as the measure of the automobile hazard, the department of commerce points out. The location of the city with reference to automobile traffic, the volume of traffic, hospital facilities and other factors should be considered. Camden is offered as an illustration of this statement. In 1931, 100 deaths attributed to automobiles occurred in Camden, but only 37 were due to accidents within the city limits. The remainder (63) were due to accidents outside.

Government Services

Course for Reserve Officers

A two weeks' course of medicomilitary training for Medical Department Reserve Officers has been arranged through the authorities of Western Reserve University and the hospitals of Cleveland, to be given, October 9-22. Mornings will be spent in hospitals and the Cleveland Clinic, which are collaborating with the school of medicine and the Pathological Institute of Western Reserve. Afternoon and evening hours will be devoted to medicomilitary subjects. Applications are being received by Dr. George W. Crile, commander of the Cleveland Inactive Duty Training Unit, Ninety-Third and Euclid Avenue, Cleveland. They will be forwarded to the corps area surgeon of the Fifth Corps Area. Those from officers outside the Fifth Corps Area should be forwarded through their respective corps area commanders. The course offered at Cleveland is the first to be given outside the Seventh Corps Area. Previous periods of study have been conducted at the Mayo Foundation, Rochester, Minn., and at Washington University, St. Louis.

Examination to Fill Vacancies in Army Medical Corps

An examination for appointment as first lieutenant in the medical corps of the regular army will be held, September 12-16. Examining boards, if necessary, will be convened at the following places, and applicants will be ordered to appear before the board most accessible to their homes: Boston; New York; Washington, D. C.; Fort Monroe, Virginia; Fort Bragg, North Carolina; Atlanta, Ga.; Fort Benning, Georgia; Columbus, Ohio; Carlisle, Pa.; Indianapolis; Chicago; St. Louis; Hot Springs National Park, Ark.; San Antonio, Texas; Fort Sill, Oklahoma; Fort Leavenworth and Fort Riley, Kansas; Fort Omaha, Nebraska; Fort Snelling, Minnesota; Denver; Cheyenne, Wyo.; El Paso, Texas; Los Angeles and San Francisco; Fort Lewis and Vancouver Barracks, Washington. Successful candidates will be ordered to an army general hospital or a large station hospital as first lieutenant of the medical reserve corps on active duty for a period not to exceed one year. After a period of observation, those applicants demonstrating necessary qualifications will be commissioned in the medical corps of the regular army to fill existing vacancies. To be eligible for appointment, the applicant must be a male citizen of the United States between the ages of 23 and 32 years, a graduate of an acceptable medical school, and must have had at least one year's hospital training subsequent to the completion of a four years' course of instruction in such medical school or its equivalent in practical professional experience as determined by the surgeon general in each case. The examination will consist of a physical examination; examination as to moral character and general fitness, and professional examination, the last to cover anatomy, surgery, practice of medicine, physiology and pathology, materia medica and therapeutics, and obstetrics and gynecology. Further information may be obtained from the adjutant general or the surgeon general of the army, Washington, D. C.

LONDON

(From Our Regular Correspondent)

July 16, 1932.

The Museum of the Royal College of Surgeons

The annual report of the conservator of the museum of the Royal College of Surgeons illustrates anew the dominance of John Hunter in British surgery and the fitness of Sir Arthur Keith for maintaining the hunterian tradition. The museum is the greatest pathologic collection in the world, but it is much more than that. The subject of John Hunter's inquiry was not merely disease but life itself, and it was to elucidate its mechanisms that he made experiments and amassed his collection of specimens, of which the museum is but an expansion. Sir Arthur Keith is the sixth to occupy the position of conservator. Under all its conservators the museum has continued to grow with the advance of knowledge, but one feature has remained constant: the museum today is arranged in the same divisions as in Hunter's time. But each conservator showed his predilections in his report. If Hunter had to draft one he would have emphasized his wonderful series of preparations which illustrate the anatomy of function, demonstrating the manner in which circulation, respiration, digestion, locomotion and reproduction, are effected in all forms of life. His "physiologic series," as it is still called, constituted the major part of Hunter's museum, and it still forms the dominant exhibit. Under Clift and Owen the physiologic department still received first place in the reports, but it was form rather than function that held their interest. They were morphologists rather than physiologists. Quekett worked in the generation that first applied the compound microscope to the elucidation of animal structure and function. With Flower came the darwinian period, anatomy was exploited, not to throw light on function, as was Hunter's aim, but to unravel degrees of relationship and lines of descent. Under Stewart, Hunter's physiologic series again became the center of attention, and now under the present conservator, whose report is the twenty-fourth drafted by him, darwinian influences are again in the ascendent.

Hunter created his museum to serve as a great engine of biologic research, because he believed that an understanding of disease and the discovery of rational means of treatment must be based on an accurate knowledge of the processes manifested by living matter. "At first sight it does look," says Keith, "as if our museum had lost its way and was being carried in a direction which Hunter never intended. If, however, those who read the reports will look not at their outward appearance but at their inward significance, they will see that, particularly in recent years, there are signs of a return to the hunterian point of view." Thus the additions of Mr R H Burne, F R S, physiologic curator, throw light on the basal processes of vertebrate physiology—the origin of the lymphatic system, the anatomy of the gland of internal secretion, and varying arrangements of the nerves of the sympathetic system. The addition reported by the pathologic curator, Mr Beadles, show an even greater representation of preparations that illustrate the nature of growth disorders of the human and the animal body. Even in the anthropologic section of the museum, which is mainly the creation of Keith, the main search is not to trace the history of extinct and of living races but to discover the physiologic process that has given each race its distinctive anatomic characters.

At various times there has arisen in the council of the college the feeling that, notwithstanding the contribution the museum was making to surgical pathology, it was not doing all it might for the advance of surgery. Under the advocacy of Sir Jonathan Hutchinson, laboratories were built over the workrooms on the museum for the purpose of experiments, but the attempt failed because experiments on living animals were excluded. Now under Lord Moynihan the council has returned to the desirability of bringing the museum more into the service of surgery. Sir Charles Ballance has continued his experiments on nerve suture and nerve grafting, which aim at discovering more efficient methods for restoring movement and sensation to paralyzed parts. By suture of the distal end of the divided hypoglossal nerve to the sympathetic cord in the neck he has shown that voluntary movement impulses can reach muscles over the sympathetic system. Mr. L. F. O'Shaugnessy, who has worked under Sauerbruch in Berlin, is investigating problems of thoracic surgery. Mr. H. P. Winsbury White is using the museum laboratories for an experimental investigation of the manner in which infection spreads from the urethra and bladder to the kidneys; Mr. E Mortimer Woolf is studying the production of diverticula from the intestinal wall.

The Sterilization of Mental Defectives

The Central Association for Mental Welfare has expressed satisfaction in the *Times* at the recent report of the British Medical Association on the sterilization of mental defectives. In common with all organizations that have given consideration to the problem, the association regards it as axiomatic that no mentally defective person, as defined by the mental deficiency acts, should have children. Today the economic strain tempts many, including some local authorities, to think that by a general measure of sterilization the high cost of segregation in institutions might be avoided. But sterilization is not so simple a solution of the difficulty as it appears. It is necessary to know how far institutional care would still remain essential, however widely sterilization might be adopted; and, conversely, to know what types of defectives, when sterilized, could still be allowed to live safely under supervision in the community. The experience of the association, which includes knowledge gained in visiting the homes of defectives all over the country for twenty years, is that there is a percentage of defectives who can be, and many of whom are, usefully employed in the community. But in some of these cases the danger of propagation is great, and for such the association holds sterilization to be desirable. It should therefore be legalized, provided adequate safeguards can be devised against abuse. But the association cautions against expecting too much from this remedy. While there is general agreement that mental deficiency is largely the result of morbid inheritance, all the available evidence indicates that the proportion born of a parent who is actually defective is small. In the majority of cases the defect is not transmitted directly, but indirectly through "carriers."

The Changing Population of London

The 1931 census shows that the decline in the population of the central or administrative part of London continues while that of the outer districts, which make up "Greater London," increases. In the former the population in 1931 was 4,397,003, a decrease on that of 1921 of 87,520. In Greater London, which is roughly included in a circle of 15 miles radius from Charing Cross, the population was 8,203,942, an increase of 723,741 in the same period and thrice as great as the increase of the previous decade. In 1801 the population of administrative London was less than 1,000,000. Then the number rose to 4,536,267 a century later, since which time there has been a progressive decline. A noteworthy fact is that the average size of families has been reduced by 8.7 per cent, from 3.79 persons in 1921 to 3.46 in 1931. This decline of population is as great as in the preceding decade, when the population was exceptionally depleted by men killed in the war. It is a manifestation of the general decline of the birth rate throughout the country. A satisfactory feature is that there is less overcrowding. Overcrowding is estimated by the number of private families with a density of more than two persons to a room. The percentage of such families has fallen from 16.1 in 1921 to 9.6 in 1931.

Females are in excess of males in the proportion of 1,151 to 1,000, a proportion which is only a little less than that of 1921 (1,165 to 1,000) just after the war, in which so many males were killed, and greater than the prewar proportion of 1911 (1,127 to 1,000).

Dangerous Drugs

So many complaints have been received recently by the police with regard to the relative ease with which dangerous drugs are obtainable in London that detectives with special knowledge of the methods of drug smugglers have been detailed to make an investigation. It is alleged that cocaine and diacetylmorphine are being sold at certain night clubs and dance halls, and that a profitable trade is derived from supplying noxious drugs for small parties arranged by persons carrying on the traffic. When drug peddling became a serious menace in London, some years ago, drastic legislation was introduced, which provided that persons who even offered or agreed to procure dangerous drugs rendered themselves liable to penal servitude, and after a number of notorious traffickers were convicted the evil was stamped out. Lately there has been a revival of the trade, shown by the number of known addicts who, according to police information, are obtaining supplies from unauthorized sources. Immigration and customs officers at the sea and air ports have been asked to watch for signs of the traffic. The ordinary channels used by drug traffickers are not difficult to deal with, but state economies have resulted in such a shrinkage of preventive personnel that the detection of illicit traffic from the continent is a serious problem. Apart from regular landing places there are miles of unprotected coast on which motor boats might discharge illicit drugs worth a small fortune to persons prepared to take the risk of detection.

PARIS

July 6, 1932.

The Treatment of Alimentary Allergy

Mr. Charles Richet, Jr., and Mr. Couder have communicated to the academy a method to combat alimentary anaphylaxis. If the method is confirmed by others, it will render great service in these conditions, for the control of which therapeutics has at present only complicated procedures, such as the peptone therapy of Pagniez and of Vallery-Radot and the elimination method of Albert Rowe. Richet uses an entirely different principle, which he has described in an article in the *Presse médicale*. He says that it is difficult to produce an anaphylactic state by way of the digestive tract. It can be accomplished only by cleansing previously the intestinal mucosa, as Besredka has advised, by an abundant supply of bile immediately before the ingestion of the food. Richet concluded from this that one could produce the opposite effect by previously protecting the mucosa with an insulating substance, and he used for that purpose liquid petrolatum or petrolatum in a pure state, without the addition of phenolphthalein, which one finds in nearly all preparations of liquid petrolatum sold today as a remedy for constipation. In his opinion, it is the too rapid ingestion of unchanged proteins that produces anaphylaxis, and that is why Pagniez observed anaphylaxis in fast eaters. The observations of Richet include cases of recurring urticaria, Quincke's edema, painful diarrhea, dizziness and migraine arising after the ingestion of certain foods, often over a long period of years and having resisted the ordinary methods of desensitization. The treatment consisted solely of having the patient ingest a dessert spoonful of liquid petrolatum at the beginning and in the middle of each meal. In each case, the allergic disorders disappeared the next day. But the method must be carried out rather perseveringly in order to effect a cure, for, in the beginning, if the treatment is interrupted, the disorders may reappear. But they cease if the treatment is resumed.

The Danger of Allowing Psychopaths Their Liberty

The increase in the number of murders committed by the insane and by half-wits is beginning to arouse the public authorities, as well as the alienists. At the recent Congress of Legal Medicine, the chief of police of Paris deplored the fact that he was not better equipped in the legal sense and from the financial point of view. He is provided with only two inspectors for the supervision of patients who have been dismissed from asylums. However, the law of 1838 allows the prefects to "adopt whatever measures are necessary" when any persons disurb the public order and the safety of citizens. They can therefore intern agitators, but they seldom do so unless laws are violated. Dr. Claude, professor of the clinical aspects of mental diseases at the Hôpital Ste. Anne, has brought the question before the tribune of the Academy of Medicine and is seeking the means of combating the increasing number of tragedies due to insanity, as a result of the considerable number of psychopaths who have been allowed their liberty too long or who have been released after a period spent in special institutions. In the present state of affairs, it would be well to work toward the creation of a more flexible and more suitable organization for the examination of suspicious cases. The authors suggested to the academy to study specific plans, such as the creation of a medicojudicial commission with authority to intervene in all cases reported by the physicians or by the police officers. Furthermore, a more extensive surveillance of patients given their liberty would afford greater security. Finally, it would be necessary to create throughout France departments of mental prophylaxis, of which there is at present only one functioning (the one at Paris).

Polyneuritis Due to Apiol

Mr. Henri Roger of Marseilles reported recently to the academy a case of polyneuritis resulting from the ingestion of apiol. This product is no longer regularly used in France, since better methods have been devised to treat amenorrhea. It is rarely used other than by pregnant women who desire to bring on an abortion, as this substance can be easily procured in the pharmacies. The desired effect is not generally produced, but they absorb considerable quantities, and it is not rare for accidents to occur. Trillat and Thiers of Lyons and Loederich and Brûle of Paris have observed grave lesions of the liver and of the kidney. Polyneuritis under these conditions has now been observed for the first time in France by Henri Roger. But Mr. Netter pointed out that cases had been reported, during the past year, from the Netherlands, Yugoslavia and Germany. Van Ittalia of Leyden has shown that the various preparations incriminated contained tricresylphosphate, which appears to be the cause of this polyneuritis. Mr. Netter recalled the observations of polyneuritis made in the United States in connection with adulterations of the fluidextract of ginger. He requested the academy to institute an inquiry as to the possibility of such adulteration in the products sold to the public, and, in case of confirmation, to prohibit further sale of the substance, as was done recently in the Netherlands and in Hamburg. Such a prohibition will be the more easily accomplished because the preparations of apiol were suppressed back in 1928. Mr. Netter is of the opinion, in view of the possibility of such accidents, that the matter should be brought to the attention of surgeons, who, following the example of Doppler of Vienna, are using in France applications of tricresyl to the surface of the arteries of the testis or ovaries in order to effect a chemical sympathicectomy.

Immunization by Inhalation

Mr. Trillat, professor at the Institut Pasteur, who has devoted himself for many years to the study of miasmas and the propagation of infectious diseases by means of micro-organisms suspended in the air, has succeeded in demonstrating the correctness of his theories by bringing about the inverse operation;

namely immunization. He made use of the infective agent of chicken cholera, after having shown that the contagion took place in the atmosphere of the poultry houses. He sprayed into this atmosphere dilutions of cultures, attenuated microorganisms and vaccines, and brought about thus the rapid disappearance of epidemics in the infected poultry houses. Dr. Roux presented the work of Dr. Trillat to the Academy of Sciences and called attention to the great interest that attaches to the research for the arrest of epidemics in inhabited places in the case of influenza, pneumonia and the like.

(From Our Regular Correspondent)

July 11, 1932

The Antivivisectionists

The antivivisectionists in Germany do not play as big a part as in some other countries. Nevertheless it becomes at times necessary to take action against them. At a recent session of the Breslauer Medizinische Gesellschaft, Rosenfeld, with the approval of others, stated that, next to charlatanism, the antivivisectionists constitute a danger to the authority of the physicians since they make the charge that such experiments are wholly useless and serve only to satisfy sadistic desires. In refuting these wild assertions, the great accomplishments of the past fifty years must be recounted and attention called to the humane methods employed in vivisection. The eradication of great epidemics and the advances of serotherapy and chemotherapy and in the diagnosis of disease have been initiated and extended by means of animal experimentation, which applies also to numerous surgical operations. Even the animals would protest against the antivivisectionists, for they have derived the greatest advantages from vivisection. Through animal experiments the protective serums against anthrax, swine erysipelas, hog cholera, foot and mouth disease, and the like, have been developed. Furthermore, human contacts with animals have been endangered by certain diseases. Psittacosis may attack the whole family, Bang's disease may affect the caretakers of stock, and undulant fever the keepers of goats. The crass ignorance of biologic and medical matters, even in educated circles, can be combated only by constantly calling attention to the great scientific achievements. Of course, animal experiments must be carried out as conservatively as possible, for which there are in Germany legal provisions, the details of which were recently discussed in these letters.

A Geographic Study of Goiter

Privatdozent Dr. Hans Joachim Arndt of Marburg reported recently on the results of a research that he had carried out in a large series of goiter cases during his eighteen months' stay in Russia. The researches are the outgrowth of a request made by the Notgemeinschaft der Deutschen Wissenschaft to Professor Aschoff of Freiburg that he institute researches in geographic pathology and establish for that purpose a suitable working center in Russia. Goiter was chosen as the classic problem of geographicopathologic research. The research conditions were highly favorable as all the regions could be visited by the investigators and the patients could be selected and examined personally. The examinations were concerned chiefly with the field of pathology and anatomy. In the various regions of Russia the average weight of the thyroid gland in the different age groups was established and thus the "life curves" of the thyroid gland were obtained, which constitute an important criterion for the diagnosis of goiter. The average weight of the thyroid gland in the regions in which goiter is prevalent is more than three times as much as in regions in which the disease is rare. It proved possible to set up a scale from region to region with the aid of which it was possible to show that goiter depended to a certain extent on age and sex. Microscopic researches made it possible to distinguish three groups, as previous researches of the Bern and Freiburg schools had shown. The first group includes the simple enlargements of the thyroid gland, in which the structure corresponds fully to the normal thyroid gland and only a quantitative increase of the functioning tissue is observed. The second group shows a nodular enlargement, which appears to develop from cell complexes that are normally present in the thyroid gland. They present all the signs of a genuine tumor and are apparently identical with the adenoma of the thyroid gland. In the third group, in addition to an increase of the functional tissue, there are distinct changes in the tissue that correspond to the conditions that are usually observed in exophthalmic goiter. The third group claims today the chief interest of investigators, as it may develop secondarily from the first two groups. From these researches it becomes again apparent that there is no uniform anatomic basis for goiter; that, on the other hand, local factors appear to play a part and furnish the basis for the various types of goiter. Now, as in the past, the goiter problem centers in the study of the local conditions that cause the enlargement of the thyroid gland. Endogenous, constitutional factors found in the patients themselves play a secondary part, as was shown also by the researches in Russia. Nevertheless, in addition to the often discussed lack of iodine, the intensity of the solar irradiation appears to be of importance, among other things. Endemic goiter (that is to say, a simple increase of the normal thyroid gland tissue) is determined by geographic and climatologic conditions and constitutes merely a compensatory reactionary process; it is necessary in the interests of orderly body functioning and does not appear to be pathologic.

Meeting of Ophthalmologic Society

At the opening session of the Deutsche ophthalmologische Gesellschaft, Tschermak-Seysenegg of Prague spoke on Goethe's work in physiologic optics. He exalted Goethe as one of the founders of subjective physiology of the senses. From the numerous papers the following items have been abstracted: Baurmann of Gottingen found in research on the structure of the vitreous body—in contrast with the descriptions of other authors—a well developed and genuine canal extending through the vitreous body. The conception that such a canal is only simulated by a central vitreous body area of especially loose structure was rejected.

New methods for the treatment of detachment of the retina were presented by Lindner of Vienna. He described his experience in fourteen cases, with his so-called undermining method, which he regards as less violent than fixation by means of successive cauterizations (Guist). The danger of intra-ocular blurring through exudation or hemorrhage is much less. The method has, however, the disadvantage that the retina thus fastened is functionally abolished. Weve of Utrecht has worked out a diathermic procedure for the treatment of retinal detachment. The principle is based on the closure of the lesions of the retina by means of multiple microdiathermopunctures. The current tension is reduced to a few milliamperes by leaving out the inactive electrode (unipolar method). For the control of localization of the lesion, such a micropuncture is allowed to precede further punctures, and the result is judged with the aid of the ophthalmoscope. The use of the ophthalmoscope is greatly simplified by the attachment of a small corneal contact device introduced by Zeiss, whereby the drying and blurring of the cornea is prevented during the operation. This device may be useful also for the determination of the meridian after the error due to astigmatism is thereby overcome. The exact localization in connection with an extremely conservative perforating microcoagulation technic by repeated use of the ophthalmoscope effects the rapid relief of the detachment with a maximal preservation of function and a minimal danger of complications. The technic is simple. The indications are more extensive than in the Gonin technic, as even the widest lesions can be smoothly healed at one sitting.

BUENOS AIRES

June 15, 1932.

Cyanosis Caused by Alveolar Hypoventilation

Dr. B. A. Houssay recently delivered a lecture before the Academia Nacional de Medicina of Buenos Aires on insufficient oxygenation of the arterial blood in patients with Ayerza's disease. Ayerza described, using the term "black cardiac patients," a certain type of patients with chronic bronchial or emphysematous disturbances, who present a clinical picture of cyanosis associated with an increase in the red blood cells, somnolence and other symptoms. Because of the cyanosis, the patients seem to be suffering from cardiac decompensation although they really are not. Later the cardiac insufficiency appears and the cyanosis increases. The speaker and his assistant Dr. I. Berconsky have observed several cases of Ayerza's disease at the Instituto de Fisiología of Buenos Aires. In all cases arterial cyanosis was present. The hemoglobin of the blood had an oxygen saturation of from 75 to 85 per cent of its volume instead of 95 per cent, which is normal. The imperfect saturation of the hemoglobin with oxygen was caused by the low pressure of oxygen (from 53 to 78 mm. instead of 100 mm.), as well as by the high pressure of carbon dioxide. Cyanosis was caused by the diminution of alveolar ventilation since the inspired air measured only from 250 to 300 cc., instead of 400 to 500 cc. Cyanosis caused by insufficient oxygenation of the arterial blood may be either acute or chronic. The acute form is observed in the superficial and rapid respiration; the chronic form is observed in several emphysematous or sclerous diseases, such as pneumonoconiosis, bronchogenic or pleurogenic disturbances, sclerosis complicated by pulmonary arteritis, and some other similar conditions. The disease of the Andes or erythremia from high altitude, described by Monje, probably is a form of alveolar hypoventilation. One should consider that alveolar hypoventilation exists whenever the pressure of oxygen of the alveolar air is lower than the barometric pressure of the locality in which the patient lives.

Undulant Fever

The national committee appointed in September, 1931, to study undulant fever in Argentina has presented a report. The first positive results of the seroreaction in man was observed in Córdoba by Dessy and Lorenzelli in 1922. The first case in which a positive diagnosis was made occurred in Mendoza in 1931. The first focus in goats was discovered by Sordelli and his collaborators. During the year 1931, 136 cases were observed in man, with six deaths, or 4.4 per cent. The clinical diagnosis was correctly made during an early period of the disease only in eight cases out of sixty-one cases of undulant fever which were observed in the several provinces, probably owing to the fact that the disease was unknown in the country. Several foci of undulant fever were discovered in twelve provinces and territories, the total number of which amounted to 230 foci during the year 1931.

Regulating the Universities

Several bills have been presented before congress in an attempt to bring about order in the several universities of Argentina. The bill proposed by members of the national executive powers has the following considerations: Since the universities should be considered as centers of investigation and teaching, it seems advisable to grant 10 per cent of the total amount collected from the revenue tax to support the expenses of schools and universitary centers. Free teaching in colleges seems advisable, while the limitation of the number of attendants to the schools does not. Teaching should be given by full time professors, who should obtain better salaries than those given to professors who are not full time teachers. The universities should be granted complete autonomy. The administration board in each faculty will consist of a group formed by a council of seven regular professors, four substitute teachers and four students. Several other bills have been offered for consideration. Some bills which have been presented before the government are inspired either in an open demagogic spirit or in absolute ignorance of matters related to a university.

Journals of the Asociación Médica Argentina

The Asociación Médica Argentina will merge three of the journals which heretofore have been published separately under the names of *Revista de la Asociación médica argentina*, *Revista de medicina interna y de tisiología* and *Revista de especialidades* into one which will be named *Revista de la Asociación médica argentina*. This journal will be published monthly and will contain the articles presented before the confederated medical societies of internal medicine, phthisiology, ophthalmology, otorhinolaryngology, psychiatry and neurology, pharmacology and therapeutics, toxicology and legal medicine, hygiene, and some other medical societies of Buenos Aires. The articles presented before the Sociedad Argentina de Biología and its branches will continue to appear, as they have appeared heretofore, in the journal *Revista de la Sociedad argentina de biología*.

TURKEY

(From Our Regular Correspondent)

Ankara, June 25, 1932.

Early Obstetrics in Turkey

Prof. Besim Omer Pasha, head of the department of obstetrics at the medical school, where he has been teaching now for forty-seven years, has recently added to his many publications a small book on the history of obstetrics in Turkey. It has been written for laymen and midwives. Among the fifty illustrations are those of some early western and eastern methods in obstetrics; in connection with the early practice of obstetrics in Turkey, three are especially picturesque: One is the preparation of the floor bed with a charcoal brazier at the side in a room with latticed window, under which there is the customary low settee. The second shows the old midwife taken from her home at night to attend a birth, mounted on a donkey and accompanied by the husband of the woman to be confined, who is carrying the lantern, and by the night watchman, who is carrying the specially constructed chair on which the parturient is to be placed. The third shows a case of asphyxia neonatorum with the midwife placing the dead child on a small table; the placenta, with which the child is still connected, is placed on a grill over a charcoal brazier, and the midwife is trying to bring life back by blowing air into the placenta with a pair of bellows.

An interesting account is given from the pages of Evliya Tchelebi, an ecclesiastic of high rank, of Esmahan Kaya Sultan, a daughter of Sultan Murad IV (1623-1640), who died during childbirth at the palace on the Golden Horn. Of this event we read that "forty persons had been reading the Koran from beginning to end, 40,000 prayers had been said during the night, a generous amount of money had been distributed among the poor, and 500 women and children who had spent the night at the gates of the palace waiting for news had been provided with new clothing. Great was the joy of the people when the birth of a daughter was announced: but when it was learned that because of an oversupply of adipose tissue the placenta was sticking to the heart of the lady sultan, their rejoicing turned into infinite sorrow. That the placenta might be delivered, the lady sultan was put into a kelim and swung right and left; she was twice hung up with her head down and then was put into a honey barrel filled to the brim with orange blossom water; when after three days the placenta was still not forthcoming, one of the midwives oiled her hand and arm with almond oil and inserted her hand and arm up to the elbow into the pelvis; after a few moments she produced a piece of tissue, saying 'at last the placenta.' A second midwife said 'there should be more of it.' Then she introduced her hand and brought out additional pieces of tissue. Undergoing such torture, the mighty Sultan's beloved daughter closed her eyes for ever the next day."

Then the author gives a short description of superstitious practices in connection with complicated births among primitive peoples, and of obstetric practices in Turkey before the days of trained midwives. At that time when the only preparation a midwife had was an apprenticeship, the contents of her bag were a bottle of olive oil, a jar of petrolatum, a scalpel, a pair of scissors and the root of an herb known as the "hand of mother Mary." The root was cleared of the soil by just putting it into a bowl of water for a while previous to introducing it into the cervix. Birth facilitating qualities were ascribed to the use of holy water, the wearing of a belt with Koran inscriptions, the keeping of a candle, a sword or a turban from the mausoleums of the great in the confinement room, and the drinking of water from the palms of the husband's hands. If she attended a primipara, the midwife would bring a specially constructed chair, much like the high chairs now in use for children, from which immediately after the birth of the child the woman was carried to the floor bed, which procedure often must have been the cause of severe hemorrhage.

The author's comment on the history of medical education throws an interesting sidelight on the development of obstetrics. He refers to an address which he delivered on the occasion of "medical day," when he said: "Looking west, we find that classical medical education was instituted only one century ago; looking east, we find that the teaching of medicine can be traced back at least six centuries. Why not regard as our first teaching center the school and hospitals established in Kayseri by the Seljuks instead of the school established under Sultan Bayezid 200 years later in Brussa.

Obstetrics did not occupy a special place in the curriculum of early Turkish institutions; only in the books on surgery are found chapters on medicaments to be used, and measures to be taken in complicated births, from which may be inferred that the obstetrics was being taught together with surgery. In the illustrated surgical handbook written in 1465 by Sherefeddin Ali are discussions and illustrations of retractors and other instruments some of which were much like those used by Ebulkasim.

At the imperial medical school founded by Sultan Mahmoud II in 1826 in Istanbul there was a more progressive curriculum. At this period religious fanaticism did not permit the dissecting of human bodies and anatomy still had to be studied from manikins. In 1836 the medical and surgical departments were merged, and Professor Bernard of the Vienna medical school became the director. The school was reorganized along European lines, and henceforth the students had the opportunity to observe Professor Bernard perform necropsies at the Austrian hospital. In 1843 the first courses for midwives were organized and in 1845 the first certificates were issued. The first special course in obstetrics for physicians was organized in 1852 and soon the translation of obstetric textbooks from French into Turkish began. Then about 1880 a number of honor students were sent to France for postgraduate work along special lines. In one of these groups was Dr. Besim Omer, who specialized in obstetrics and pediatrics under Professor Budin of Paris and on his return in 1885 was appointed lecturer on obstetrics at the medical school in Istanbul. At first, Sultan Abdul-Hamid II (1875-1908) favored the professors in the medical school but later, anticipating a possible political influence, saw to it that the number of physicians allowed to engage in postgraduate work in France or Germany was restricted. But by the time of the adoption of the constitution in 1908 a great number of physicians had availed themselves of the opportunity to do postgraduate work abroad. While Besim Omer Pasha is an advocate of the French school and French methods, the late Dr. Asaf Dervish Pasha, professor of gynecology at the medical school and author of "diseases of women," advocated German methods. Both may be regarded pioneers of obstetrics in Turkey for to both belongs the honor of having paved the way for the establishment of scientific obstetrics. It was not easy to overcome the reluctance of Turkish women to seek the advice of physicians; fifty years ago it was still customary for women in childbirth to be attended exclusively by midwives. It required patience and tact on the part of those early obstetricians to overcome that reluctance at first in the homes of the wealthy and then gradually in the outpatient departments of the hospitals, where in the beginning many a young woman refused to lift her veil or give her proper age.

ITALY

June 15, 1932.

Convention of Sport Physicians

The first national convention of sport physicians was held in Rome. The chairman, Professor Baglioni, director of the physiologic institute of the University of Rome, in his opening address, discussed the duty of the modern physician in connection with sport activities. Sport physicians should supervise and direct all matters affecting the musculature, the brain and the psyche that come up in any form of sport activity and collaborate in raising the physical and moral standards of young persons who engage in sports. Improvement of the individual and of the race constitutes part of the purpose of preventive medicine, which has as its bases physiology and morphology. This convention of sport physicians planned to consider, as the central theme, the biologic evaluation of participation in sports from age 18 on. Only one topic was considered: "The Physical Evaluation of the Sport Devotee." Papers were presented by Professors Cassinis, Talenti and Bucciardi and Dr. Viziano.

Professor Cassinis dealt with anthropometric and morphologic evaluation of sport devotees. The purpose of the anthropometric evaluation is to show, on the one hand, the capacity to withstand the hardships of sport, and, on the other hand, the candidates' capacity to accomplish in the various sports. The anthropometric measurements, carried out by the Viola method, for the purpose of constitutional morphologic evaluation, and supplemented by the functional examination of the various organs, are designed to secure an exact method of reaching an opinion not only as to robustness but also as to the candidate's respective ability in sport. Dr. Viziano dealt with the evaluation of the cardiocirculatory apparatus, emphasizing that it is above all necessary to ascertain the reserve energy of the heart by observing the influence that participation in sports exerts on the circulatory function. Studying the size of the heart after a physical effort, the speaker noted that only when the fatigue overcame notably the reserve force of the organism was there acute dilatation of the myocardium. Since previous infectious diseases may have an influence, before the training of a subject is begun his personal history should be taken. With regard to arterial, venous and capillary pressure in relation to sports, the speaker urged that account be taken of the individual's occupation—a factor that is often overlooked—lest fatigue be added to fatigue. It is necessary to select carefully the teams in order not to force too much the reserve strength of any subject, while the energies of the others are not used sufficiently.

Dr. Talenti spoke on the evaluation of the respiratory apparatus. He discussed the oxygen requirements, the carrying of oxygen to the muscles and the behavior of pulmonary ventilation, which he recorded with a spirometer of his own manufacture. In conclusion, he affirmed that, in labor, greater importance attaches to an increase in the depth of breathing than to the frequency of the respiratory acts. Professor Bucciardi spoke on the evaluation of the neuromuscular apparatus, for which, the speaker emphasized, it is difficult to set up a rigid system. The criteria of evaluation must be based on multiple conditions and must take account of numerous factors. Bucciardi demonstrated the use of an ergograph that enables the examiner to record graphs when the arm is maintained in any position whatever. The official papers on the main topic having been completed, further communications on kindred topics were presented.

Professor Martinez spoke on the influence of sport on the constitution of the female genitalia, stating that from numerous observations that he had made in Bologna it appeared that rational abdominal gymnastics is useful for the development of the pelvis and of the female genital apparatus. "Athletics for Women" was the topic chosen by Madame Professor Zanetti and Professor Baglioni. The conception was brought out that sport activities, since born of the need for exercise, stimulate the regular development not only of the muscles but also of the heart, the respiratory apparatus and the kidneys.

It was decided to hold next year a second national convention at Bologna, or possibly to announce an international convention to be held at Rome.

Prophylaxis of Typhoid

The general manager of the public health service (ministry of the interior) has sent to the "provincial physicians" a circular letter concerning regulations pertaining to the hygiene of the soil and of dwellings and to the prophylaxis of typhoid. The sanitary authorities are urged to promote work directed toward the improvement of sanitary conditions of the soil in urban and rural communities and to prevent the improper disposal of waste waters from households and to inquire into the state of maintenance of the drains, cisterns and wells. The various systems of defense against flies are to be applied, especially in places where there are patients with infectious diseases. The vigilance with respect to food products and drinking water is to be intensified. In localities where typhoid is endemic, the causes that maintain the contagion will be sought out and measures will be taken to suppress them. A prompt diagnosis of suspected cases will be provided and search for carriers of Bacillus diphtheriae will be made among the members of the patients' families. Hospitalization of patients will be encouraged. Antityphoid vaccination will be extensively applied, especially in localities that are the seat of epidemics.

Marriages

William G. Stephenson to Miss Mamie Louise Barnes, both of Chattanooga, Tenn., June 15.

Randolph L. Anderson, Richmond, Va., to Miss Ruth Grove of Lewisburg, Pa., June 30.

George O. Thompson, Alliance, Ohio, to Miss Gwendoline Copeland of Cleveland, recently.

Morris S. Rosenblum to Miss Mathilda J. Meritzer, both of Youngstown, Ohio, recently.

Charles Powell Cake, Detroit, to Miss Janette Osborn of Lawrenceville, Va., May 28.

James R. Bloss to Miss Musette Hollobaugh, both of Huntington, W. Va., July 14.

Roland I. Grausman to Miss Elizabeth Strauss Block, both of New York, July 30.

Joseph J. Kronzer, Oshkosh, Wis., to Miss Lucille Wagner of Cleveland, May 23.

Gamber F. Tegtmeyer, Milwaukee, to Miss Margaret Louise Brown, June 18.

Will S. Nichols, Lake City, Fla., to Miss Eleanor Haile of Live Oak, June 28.

Edgar Andrew Rygh to Miss Ernestine Kolbus, both of Chicago, July 29.

Deaths

John S. Helms ⊕ Tampa, Fla.; Memphis (Tenn.) Hospital Medical College, 1891; member of the House of Delegates of the American Medical Association from 1918 to 1922 and again in 1927; past president of the Florida Medical Association and the Hillsborough County Medical Society; member of the Southern Surgical Association; member of the board of governors of the American College of Surgeons; surgeon in chief to the Tampa Children's Home; director of the division of surgery, Tampa Municipal Hospital; aged 61; died, July 24, of heart disease.

Charles George Lucas ⊕ Louisville, Ky.; University of Louisville School of Medicine, 1890; clinical professor of gastro-enterology at his alma mater; member, secretary and formerly president of the American Gastro-Enterological Association; fellow of the American College of Physicians; served during the World War; aged 63; on the staff of St. Joseph Infirmary, where he died, July 7, of heart disease.

Arkell Roger MacMichael, New York; College of Physicians and Surgeons, Buffalo, 1882; New York Homeopathic Medical College, 1883; formerly professor of clinical medicine and applied homeopathic therapeutics, New York Homeopathic Medical College and Flower Hospital; aged 76; died, June 29, in a hospital at Santa Barbara, Calif., of heart disease.

Frank Jay Van Kirk ⊕ Bellingham, Wash.; Hamline University Medical Department, Minneapolis, 1900; member of the American Academy of Ophthalmology and Oto-Laryngology and the Pacific Coast Oto-Ophthalmological Society; fellow of the American College of Surgeons; aged 64; died, May 4, of coronary thrombosis.

William Edward Synan, Fall River, Mass.; University of Pennsylvania School of Medicine, Philadelphia, 1892; member of the Massachusetts Medical Society; aged 60; on the staff of the Union Hospital, where he died, June 14, of hypertension and arteriosclerotic heart disease, auricular fibrillation and chronic interstitial nephritis.

Victor A. Aimone, Washington, D. C.; Georgetown University School of Medicine, Washington, 1912; served during the World War; medical officer in charge of the U. S. Veterans' Administration Hospital; aged 45; was shot and killed, July 13, by a former patient.

Charles E. Lewis, Grove City, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1895; fellow of the American College of Surgeons; for thirty-six years medical missionary in China; aged 66; died, July 4, of biliary obstruction and septic cholangeitis.

Charles A. Van Dervoort ⊕ Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1893; medical director of the Fidelity Mutual Life Insurance Company; aged 65; died, July 3, in the Bryn Mawr (Pa.) Hospital, of heart disease.

Willis F. Cobb, Lyle, Minn.; Chicago Medical College, 1874; member of the Minnesota State Medical Association; for six years mayor of Lyle; formerly president of the school board; aged 84; died, June 3, of cardiac decompensation.

John Ebenezer Pressley, Abbeville, S. C.; Atlanta (Ga.) College of Physicians and Surgeons, 1908; aged 49; died, June 8, in the Emory University Hospital, Atlanta, of coronary occlusion, hypertension and arteriosclerosis.

James William Hempstid, Burrton, Kan.; American Medical College, St. Louis, 1885; member of the Kansas Medical Society; aged 71; died, May 28, at Hutchinson, of myocarditis and arteriosclerosis.

Ralph Sanders Stevens, Princeton, N. C.; University of North Carolina School of Medicine, 1905; member of the Medical Society of the State of North Carolina; aged 47; died, May 20, of heart disease.

William Leonard Jerman, Pasadena, Calif.; Eclectic Medical Institute, Cincinnati, 1873; Medical Department of Hamline University, Minneapolis, 1897; aged 81; died, May 20, of cardiorenal disease.

William I. Marsalis ⊕ Centreville, Miss.; Louisville (Ky.) Medical College, 1893; aged 58; died suddenly, May 28, of acute dilatation of the heart, coronary thrombosis and hypertension.

Harry Archibald Baker, Minneapolis; University of Minnesota College of Medicine and Surgery, Minneapolis, 1901; aged 52; died, June 8, of coronary thrombosis and diabetes mellitus.

Frederick L. Deck, St. Louis; St. Louis College of Physicians and Surgeons, 1898; aged 68; died, June 10, in the Barnes Hospital, of intestinal obstruction due to strangulated hernia.

Patrick Cleveland Simmons, Arlington, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1910; aged 52; died, May 29, in a hospital at Dothan, Ala., of meningitis.

Joseph J. Greenblatt, Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1908; aged 45; died, July 2, in the Jefferson Hospital, of erysipelas and uremia.

Robert E. Limerick, Corinth, Ky.; Medical College of Ohio, Cincinnati, 1884; member of the Kentucky State Medical Association; aged 73; died, May 28, in Cordova, of uremia.

Frank Willis Corson, Tidioute, Pa. (licensed, Pennsylvania, 1882); member of the Medical Society of the State of Pennsylvania; aged 71; died, May 16, of myocarditis.

William Harwell Hodson, Los Angeles; Bellevue Hospital Medical College, New York, 1882; aged 73; died, May 9, of thrombosis of the coronary and cerebral arteries.

Harvey Gill Baldwin, Seagoville, Texas (licensed, Texas, under the Act of 1907); aged 71; died, June 8, in Dallas, of cerebral hemorrhage and arteriosclerosis.

Benjamin Coe Irwin, Springdale, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1889; aged 68; died, June 15, of cardiorenal vascular disease.

Jasper E. Wagner, Paris, Ohio; Starling Medical College, Columbus, 1896; aged 64; died, May 30, of pulmonary edema, myocarditis and mitral stenosis.

Henry D. Rickenbach, Pittsburgh; Medical Department of the University of the City of New York, 1887; aged 72; died, June 2, of acute myocarditis.

Grant J. Pollard ⊕ Oriskany Falls, N. Y.; University of Vermont College of Medicine, Burlington, 1890; aged 66; died, May 15, of endocarditis.

George Robertson, Eolia, Mo. (licensed, Missouri, 1900); member of the Missouri State Medical Association; aged 67; died, June 13, of septicemia.

James Edward Orr, Detroit; McGill University Faculty of Medicine, Montreal, Que., 1886; aged 70; died, June 14, of carcinoma of the sigmoid.

Amzie B. Jenkins, Waxahachie, Texas; Vanderbilt University School of Medicine, Nashville, Tenn., 1876; aged 78; died in June, of senility.

William Roberts, Denver; Denver and Gross College of Medicine, 1906; aged 64; died, June 20, in Fitzsimons Hospital, of carcinomatosis.

Cornelius S. Powell, Somerville, Tenn.; Meharry Medical College, Nashville, 1909; aged 53; died, June 10, of cardiorenal vascular disease.

Le Roy B. Sherman, New York; New York Homeopathic Medical College and Hospital, 1889; aged 72; died, June 15, of diabetes mellitus.

Winfield W. Pulliam, Dow, Ill.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1883; aged 81; died, June 5, of diabetes mellitus.

Horace Hobart Hollister, Cody, Wyo.; Long Island College Hospital, Brooklyn, 1874; aged 91; died, May 31, of chronic myocarditis.

James J. Beaty, Jennings, Fla.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1893; aged 70; died, June 22, of heart disease.

Hanna Burroughs Mulford, Haddonfield, N. J.; Cleveland Medical College, Homeopathic, 1892; aged 88; died, June 9, of arteriosclerosis.

William J. Davis, Los Angeles; Chicago Homeopathic Medical College, 1888; aged 70; died, May 11, of carcinoma of the prostate.

William D. Swaney, Columbia, Mo.; Medico-Chirurgical College of Kansas City, Mo., 1903; aged 59; died, June 4, of heart disease.

Cyrenius C. Sayles, Langston, Mich. (licensed, Michigan, 1900); Civil War veteran; aged 92; died, June 19, of cerebral embolism.

Charles T. Donohoe, Chicago; Jenner Medical College, Chicago, 1910; aged 63; died, July 25, of chronic myocarditis.

James Jaynes, Sneedville, Tenn. (licensed, Tennessee, 1889); aged 82; died, June 27, of nephritis.

John W. Hornby, Newark, Ohio; Columbus Medical College, 1888; aged 74; died, May 9.

Bureau of Investigation

THE B. & M. CASE

The Government Wins a Hard-Fought Case Against a Fraudulent Consumption Cure

The lay public, and even a large part of the medical profession, has little idea of the terrific odds against which federal officials have to work in order to protect the public against fraudulent nostrums. Following the Johnson case of some years ago, the United States Supreme Court decided in a divided opinion that the statement in the original Food and Drugs Act to the effect that any medicine which bore on its label a statement which was "false or misleading in any particular" really meant statements which were false or misleading in certain particulars, namely, only those relating to composition and origin and not those relating to therapeutic effects. This blow to the law resulted in a special message being submitted to Congress by the President, urging an amendment to the law that would specifically cover false claims for curative effects. The Sherley Amendment was the result. This amendment, in its original form, declared, in effect, that a "patent medicine" for which "false or misleading" therapeutic claims were made would be deemed misbranded. Due, however, to the political power of the "patent medicine" interests, this phrase was changed before the bill was passed to read "false and fraudulent."

As a result, federal officials, in order successfully to prosecute "patent medicine" quacks, have to prove not only that the therapeutic claims are false, but also that the manufacturer, in making such claims, has been guilty of intentional fraud. Only those who are familiar with court procedure can have any idea of the difficulties besetting the federal officials in their efforts to prove to the satisfaction of a lay jury that the exploiter of a "patent medicine" had not only lied about his product, but *knew* that he had lied!

On July 19, 1932, in the Federal District Court, Baltimore, a flagrantly fraudulent "patent medicine" known as "B & M" was declared misbranded. The case consumed more than three weeks and was considered by the officials of the Food and Drug Administration to be one of the most important in the history of the administration of the Food and Drugs Act. B & M, according to the testimony given in the trial, was originated by one W. P. McClellan who owned a livery stable and used B & M on his horses. F. E. Rollins, the present chief owner of B & M, was a bookkeeper for McClellan and gradually *acquired more and more stock in the* B & M company and finally purchased McClellan's interest. Rollins had also been a court reporter and used his knowledge of the rules of court evidence to his advantage in the present case.

B & M Remedy is marketed from Boston by the F. E. Rollins Company. It is a simple liniment of, essentially, turpentine, ammonia and egg. It used to be known as "B & M External Remedy" and the name of the company used to be the National Remedy Company. The stuff has always been sold as a remedy for such serious conditions as tuberculosis, pneumonia, influenza, and a number of other pathologic states.

Some twelve years ago the National Remedy Company was prosecuted in Massachusetts under the fraudulent advertising law of that state. The case was brought by Dr. William C. Woodward, who at that time was Commissioner of Health of Boston, but is now Director of the Bureau of Legal Medicine and Legislation of the American Medical Association. Dr. Woodward was successful in this suit and the concern was found guilty. To the best of our knowledge, this is the only case on record in which a "patent medicine" exploiter has been found guilty under a state law governing fraudulent advertising—although every state has such a law and such laws are probably violated every day of the year.

In 1922 the federal government brought a case against B & M, but because of lack of preparation on the part of the prosecution and an underestimate of the legal tactics of the exploiters of B & M, the nostrum concern won. Later the government made further seizures of B & M and in 1929 the company consented to a judgment of condemnation. They persisted, however, in selling their stuff as a cure for tuberculosis in spite of warning from the officials of the Department of Agriculture that in certain statements printed on the bottle, label and carton and in the literature accompanying the goods, they were violating the national Food and Drugs Act.

THE PRESENT CASE

In the case that has just been decided, the government brought suit against the F. E. Rollins Company, by way of seizure of this firm's goods, because of false and fraudulent claims for therapeutic effects made for the preparation in a booklet issued by the company. The trial lasted three weeks and was tried in the United States District Court at Baltimore before Judge W. Calvin Chesnut. Mr. Simon E. Sobeloff, district attorney at Baltimore, was counsel for the government.

The lawyer chiefly concerned in defending the F. E. Rollins Company was Melvin M. Johnson—who also is president of this "consumption cure" concern. Mr. Johnson, who was called also as a witness, testified that he is a member of the Massachusetts Bar Association, of the American Bar Association, a founder and life member of the American Law Institute, a professor in Boston University Law School, a trustee of Tufts College and *Chairman of the Board of Visitors of Tufts Medical School!* [Italics ours.—Ed.] Mr. Johnson had acted as counsel for the nostrum concern in its various other brushes with the authorities. It may be interjected at this point that it is not at all uncommon for a "patent medicine" concern to have a lawyer as an officer of its company. From a practical point of view, a lawyer and an advertising man are much more necessary to commercial success in the selling of quack remedies than is a physician or a pharmacist.

The government introduced as witnesses nineteen national authorities in the fields of medicine, surgery and pharmacology, who testified to the falsity of the claims made for B. & M. The sum and substance of the evidence given by these men was to the effect that B. & M. was not an effective treatment for tuberculosis and the other diseases mentioned. The physicians who aided the government were Drs. E. M. K. Geiling, Lewellys F. Barker, Samuel Wolman and Arthur Grollman, all of Johns Hopkins University; J. W. Sever of Boston; Victor Cullen, Superintendent of the Maryland State Sanitarium; Cleaveland Floyd of Harvard University; John B. Hawes, II, of Boston; Lawrason Brown of Saranac Lake; Gordon Wilson of the University of Maryland; Robert Kerr, Director of Tuberculosis Control Work of New Hampshire; Carl C. MacCorison, Superintendent of the North Reading Sanitarium, Mass.; J. F. McMurry of New York City; Clarence R. Hines, Amesbury, Mass.; Charles Kaufman of New London, Conn.; Lewis J. Battle and Caryl Burbank of Washington, D. C.; Paul Turner, Superintendent of the Kentucky State Sanitarium, and Robert Soutter of Boston.

THE TESTIMONY OF DAVID L. MARTIN

The only physician who went on the stand for the F. E. Rollins Company was the concern's "medical adviser," Dr. David L. Martin of Boston. Dr. Martin's testimony in the case gave eloquent evidence of his scientific background. After testifying that he was thirty-five years old when he was graduated by a homeopathic school, and prior to taking his medical course had been a preacher for nine years and that his congregation paid his way through medical school, he told the jury that he first heard of B. & M. when he was called to treat a patient with pneumonia. Dr. Martin said that he had prescribed Antiphlogistine, but that the patient's family suggested the use of B. & M. and Dr. Martin agreed that it was all right to use it. Later, he said, F. E. Rollins came to see him and, as Dr. Martin put it, "explained the work that he was doing with B. & M. and it appealed to me . . . so we have been working together ever since." Dr. Martin further testified that B. & M. was such a wonderful preparation that, when applied, the character of the eruption that it invoked indicated the nature of the ailment for which the patient was being treated! To quote from Dr. Martin's testimony:

> "Now, if a man has the flu, he will get an eruption of the vesicles filled with water; if it is t. b., we get an eruption with a little black pin head, mottled or pin head; if it is a mixed infection, we will get sometimes as large as the thumb-nail where the skin will slough right off."

Nor was this the only esoteric quality of B. & M. When Dr. Martin was asked if he had had any experience in treating a kidney infection with this "patent medicine," he replied:

> "Applying it over the kidney sometimes it will outline almost the absolute spot on the outline of the kidney on the back. I have had large abscesses drawn right out on the back from the use of B. & M."

Dr. Martin also described in his testimony cases of men and boys who had run nails through their feet, with resulting "blood poison," and on which he had used nothing but B. & M. When asked if he had never used tetanus antitoxin, he testified that he had not. When the Court expressed surprise, Martin said that while tetanus antitoxin was the routine treatment, he had never used it, but always used B. & M. and had never had any failures. He added, in answer to the judge's question, that he considered B. & M. "a sufficient substitute for anti-tetanus serum." Mr. Sobeloff, attorney for the government, asked Dr. Martin what he knew about tetanus as to its nature, and he replied that he knew nothing. But the attorney pointed out that as he had treated tetanus with B. & M., he must be familiar with the disease. Then followed this testimony:

Mr. Sobeloff.—What is tetanus?

Dr. Martin.—It is simply rapid inroad of the streptococcus infection in the blood stream.

Mr. Sobeloff.—Is tetanus a streptococcus infection or is tetanus an infection peculiar to itself of a specific germ?

Dr. Martin.—Well, I don't know that they have isolated the particular germ. I was taught it was streptococcus.

The Court.—What does it come from, doctor? What causes it?

Dr. Martin.—Nobody knows. It is a germ; one of those germs.

Later, in the same piece of testimony, when Dr. Martin was asked if he knew what the tetanus bacillus is, he replied: "I don't know; I am not up on those preparations." Dr. Martin testified that at first he was paid $50 a month for helping Rollins, but that later they increased his emoluments to $75 a month.

DR. PEASE AND THE PEASE LABORATORIES

But from the standpoint of the honor of the medical profession and the protection of the public health, the most disheartening feature of the case was not the obvious ignorance of Dr. Martin, but the statements by both F. E. Rollins and the company's lawyer-president, Melvin M. Johnson, that the booklet on which the government brought its case charging fraudulent claims, had been prepared and much of it written by Dr. Herbert D. Pease of the Pease Laboratories, New York City. The contract with Pease, according to the uncontradicted testimony in the case, was that nothing was to go into the booklet that Pease could not go into court and testify to.

The testimony showed that Dr. Pease was hired first as "expert witness" by Mr. Johnson to testify in court in support of B. & M. Later, after Rollins and Johnson decided to change their "literature," Pease was employed to rewrite or edit the booklet. There was offered in evidence the manuscript of the B. & M. booklet, together with a letter with which it had been transmitted by Dr. Pease to Mr. Johnson. The letter, dated May 1, 1931, read:

> "Mr. Johnson, here is the material in a rather rough form. I trust the printer will do well with it. The tabulations should, of course, be set up evenly. There will be some proof corrections and I am not attempting to set things in detailed form tables just at present. The new plates are superior to the old. It might be well to have Mr. Fenwick see all this.
>
> Very hastily,
>
> H. D. Pease."

Both F. E. Rollins himself and his president-attorney, Melvin M. Johnson, practically rested their entire case on the fact that they had paid Pease $15,000, for which he was to revise their literature and give it a "scientific" background. This was to enable them to come into court and say, as they did say, that the best evidence of their good faith was that they had employed a physician who was supposed to rank high in his profession, who is a member of the New York State Medical Society and a Fellow of the American Medical Association, to furnish scientific evidence for the claims made for B. & M. and to permit no statement to go into their booklet that could not be supported by the man who had these qualifications.

It is worth reminding our readers at this point, that it was Dr. Pease who was alleged to have furnished a favorable report for the poisonous thallium acetate depilatory "Koremlu," as was brought out in The Journal of July 30, 1932. It is Dr. Pease who is quoted by the exploiters of the preposterous nostrum "Dur-Inda," previously known as "Lukutate." It was the Pease Laboratories that furnished the fantastic evidence for the exploiters of "Vapex," by which that concern purported to show that because a relatively large amount of Vapex, when enclosed in a small container, would give off enough fumes to destroy certain bacteria, that therefore a drop of Vapex on a pillow would kill the germs of a common cold. And B. & M., Koremlu and Vapex are by no means all of the nostrums for which the Pease Laboratories have furnished reports during the past few years.

It is significant that while Dr. Pease was present during the first part of the B. & M. trial when the government was presenting its case, he disappeared at the time when he could have gone on the stand to testify for the B. & M. concern which had hired him. His absence brought comment from the court and the preposterous implication from the nostrum interests that Pease had been intimidated by the American Medical Association. In order to get Dr. Pease on the stand the government attempted to subpoena him as its witness, but were unable to get in touch with Dr. Pease, either through his laboratory, his home, or any other place. Lawyer-President Johnson, in his closing argument, asked the jury to sympathize with the owner of B. & M. because the man (Dr. Pease) to whom he (Rollins) had paid $15,000 and who had written or checked every word in the pamphlet had "welched" and "walked out on him" at the last moment. Johnson said he would not rely on a "man who was yellow." Yet earlier in his testimony, Mr. Johnson admitted that it was he (Johnson) who had advised Rollins to employ Dr. Pease because he was a graduate of a good medical school, a Fellow of the American Medical Association, and an adviser of many large (nostrum?) concerns.

Photographic reproduction (reduced) of the front cover of the "B. & M." booklet, much of which, according to the sworn evidence in the B. & M. case, was written by, and all of which was prepared under the supervision of, Dr. Herbert D. Pease of the Pease Laboratories.

THE B. & M. BOOKLET

To return to the B. & M. booklet: About one-half of this book is made up of what is described as "Scientific Evidence," and which, according to Mr. Johnson, "was written by Dr. Pease and nobody else so far as we know." The so-called evidence is not scientific and the data that is furnished may be counted on only to confuse the lay public and to convey to that public the idea that there is a scientific basis for the use of this mixture of ammonia, turpentine and egg when applied to the chest as a means of "drawing out" the germs of tuberculosis from the lungs. Judge Chesnut, in his charge to the jury, in referring to this so-called "Scientific Evidence," said:

> "You can consider whether this scientific data thus arranged was for the purpose principally of being superficial impressions to the layman or whether it has any real value to B. & M. with regard to the diseases for which it is recommended. . . . You may possibly conclude that the effect of this arrangement of the booklet with reference to the so-called scientific evidence is to be impressive, rather than really informative."

The balance of the booklet that is said to have been prepared by Dr. Pease purports to explain the genesis of this nostrum and its method of accomplishing the astounding results claimed for it. In this we are told that while there are limits to self-medication, "the public ought to be permitted to decide those limitations for themselves." One is tempted to ask: Does Dr. Pease believe that one should leave to the decision of the lay public the advisability of self-medication in the treatment of tuberculosis, diphtheria, scarlet fever, venereal diseases, and other conditions that not only menace the individual, but menace, also, the community? The medical profession is damned with faint praise in this booklet and the charge is made that physicians are "slow to adopt and use drugs that have valuable therapeutic effects, unless the effects of those drugs are taught in the medical school." The old story is told of how the Peruvians discovered the value of cinchona bark centuries ago and how the Chinese have for generations been aware of the virtues of ma huang, both of which drugs were later to be adopted by scientific medicine. Then we read:

> "We are obtaining much information concerning some of the ways in which B. & M. works to do the good which we know from actual and practical use that it has done. We can show some features of it now. Meanwhile, shall we have to wait for centuries—like the doctors did before they prescribed quinine for malaria—until the doctors can prove just how the active principles of B. & M. work, before they will let their patients use it? Some doctors, we are happy to say, are broad-minded enough to use B. & M. now in proper cases."

All the way through the booklet, however, appear evidences of an attempt to lead the public to believe certain things without making definite claims for those things. In fact, the character of the booklet cannot be better described than it was by United States Attorney Sobeloff in his summing up before the jury. Said Mr. Sobeloff: "It is for you gentlemen [the jury] to say whether a man or a company can string together a lot of truths and half-truths, mysteriously, and with a wink in the eye, intimating certain conclusions without stating them, and then come into court and say: 'Nowhere do we use the word "cure".' "

The booklet records that Rollins, the chief owner of B. & M., believes that B. & M. actually penetrates to the seat of tuberculous infection and kills the germs themselves. Then follows this disingenuous statement, presumably by Pease:

> "We want to say frankly that we are not now able to prove by scientific and legally competent evidence that this is true. Neither has it been demonstrated to our satisfaction that it is not true."

B. & M. AS A CONSUMPTION CURE

In that part of the booklet giving directions and alleged information on the treatment of lung trouble by B. & M., a booklet, let it be remembered, that was declared under oath to have been prepared or approved by Dr. Pease, we read:

> "B. & M. gives great relief after the first few weeks and progress toward recovery is undoubtedly hastened by careful devotion to its free and persistent application according to directions."

Then follows an elementary description of how the tubercle bacillus attacks the lungs and how necessary it is to build up "body resistance." Then:

> "We commend all efforts toward such building up of resistance. We believe that the persistent use of B. & M. as recommended gives great aid toward that end . . . It helps to open up those lung areas which may have collapsed and in which the life processes have stagnated, if it can be brought into contact with them."

Later follows specific directions for the treatment of a patient with tuberculosis of the lungs: The patient should lie down and B. & M. should be poured on the chest, throat, sides and back, over the entire lung area. It should be spread on evenly at least six times at a sitting, and there should be at least two and preferably three daily applications of this kind. The turpentine and ammonia are likely, of course, to produce an eruption, in which case apply "Ex-Rem Ointment" —also put out by the F. E. Rollins Company.

In cases of tuberculosis of the throat, B. & M. should be applied as already directed and frequent inhalations of the stuff also taken, and it may be advisable to use a spray consisting of one part of B. & M. and ten parts of water. Tuberculosis of the cervical glands should be treated by regular free applications of B. & M., and the same methods used in cases of tuberculosis of the joints and other parts of the body.

In pneumonia, B. & M. is to be applied hourly, and the same method is to be used in treating influenza, except that in the latter it is to be applied to the entire trunk of the body.

In whooping cough the "paroxysms are often promptly relieved by frequent applications of B. & M. to the throat and upper chest." In rheumatic fever we are told that "if B. & M. is properly used at the first attack, the infection of the [heart] valves may never occur."

In cases of "blood poisoning," B. & M. is to be spread upon the part infected for twenty or thirty minutes. In acute rheumatism B. & M. will "help to allay inflammation of the joints or muscles," while in the chronic form of this disease "inflammation and pain may be expected to disappear and the joints become more flexible." The cautious injection of the phrase "may be expected" is again indicative of the character of the booklet.

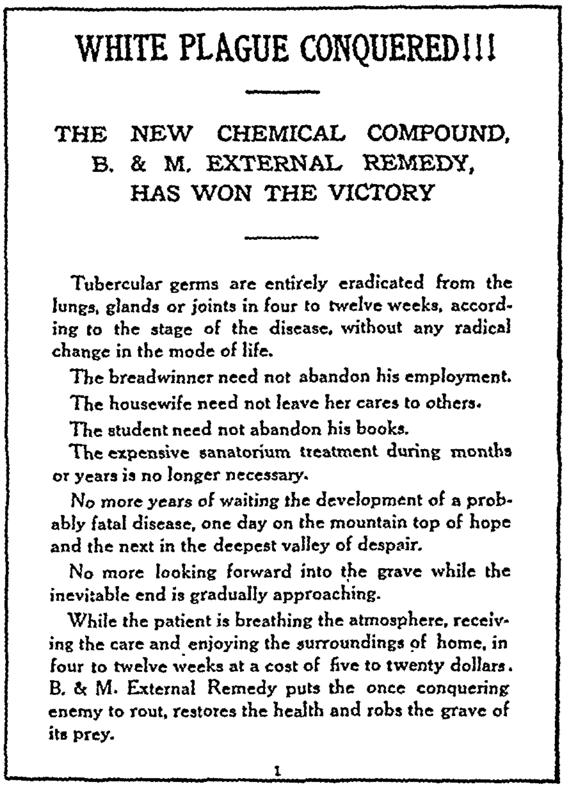
THE FENWICK "RESEARCH"

In addition to money paid to Dr. Pease, Rollins testified that he had had "research" work done in the Long Island Hospital, Boston, under one H. Benson Fenwick of that institution. Fenwick is now dead. The work, according to Rollins, was done on tuberculous patients and Fenwick was paid no less than $80,000 for the work! In some of the booklets issued prior to the "Pease booklet" there were reproduced what purported to be facsimiles of reports by Fenwick. One of these was written—wholly without the knowledge or authority of the institution—on the stationery of the Massachusetts College of Pharmacy and was dated August 20, 1926; another, almost identical in wording, was on Fenwick's own stationery and dated August 1, 1927; still another, also on Fenwick's stationery and nearly identical with the other two, was dated August 1, 1928. President-Attorney Johnson said that the physicians who had done the work with B. & M. at the Long Island Hospital would not testify for B. & M. because they were afraid to. Rollins testified that Fenwick told him that a report of the alleged successful clinical trials of B. & M. at the Long Island Hospital had been prepared and submitted to Dr. Soutter of the hospital, and was to be published in a St. Louis medical journal. Dr. Soutter was later called as a witness by the government and declared that he never heard of B. & M. or of the alleged clinical work for which Rollins paid $80,000.

The sales of B. & M. in 1928 amounted to $140,000, in 1929 to $140,000, in 1930 to $130,000, and in 1931 to $110,000. The net profits in 1926 and 1928 ran as high as $22,000. Rollins' personal salary has varied from $1,200 to $10,000, and since 1924 the concern has paid out nearly $100,000 for alleged scientific investigations and approximately $25,000 for legal expenses. What proportion of these huge sums represents the blood-money of impoverished and deluded consumptives?

During the trial, the B. & M. concern called to the stand a number of lay witnesses who alleged that they had been benefited or cured by the use of the liniment. The government proved, however, that some of these witnesses were still tuberculous and that in some instances the use of the preparation had caused considerable harm to the patient. A testimonial widely used by Rollins, it was shown by the government, had been written by a person who received checks at very definite intervals from the Rollins concern and who finally died of tuberculosis. Rollins himself, when on the stand, attempted to convince the jury that these checks were merely sent out of the goodness of his heart because the person who had given the testimonial was in need of money. The B. & M. concern also called, as one of its many witnesses, a middle-aged man who claimed that while he had been a sufferer from tuberculosis and had treatment in a number of sanitariums without relief, he had been cured several years ago by the use of B. & M. Attorney Sobeloff for the government, however, conclusively proved that this man who had claimed to be cured still had an active tuberculosis and had, in the very recent past, not only submitted a sample of his own sputum to a state sanitarium, but had undergone an x-ray examination which proved the presence of tuberculous lesions in both lungs. In fact, the cases brought in as witnesses at the trial developed essentially the same facts that had been developed by the Bureau of Investigation of the American Medical Association, which had, by correspondence, traced certain B. & M. testimonials to their sources: Namely, those persons who really had tuberculosis and had relied on B. & M. were either dead or still suffered from the disease. Others, who were well, had never had the disease!

Rollins and his associates argued that the word "remedy" has various meanings and that it should be interpreted as anything which would have a curative or alleviative effect in the treatment of disease. He emphasized that he did not use the word "cure." Judge Chesnut, however, in his charge to the jury, cut through the sophistries and instructed the jury that the standard dictionary meaning of the word "remedy," as implying a substance which had substantial worth in the cure of disease, was the one to be adopted.



WHITE PLAGUE CONQUERED!!!

THE NEW CHEMICAL COMPOUND,
B. & M. EXTERNAL REMEDY,
HAS WON THE VICTORY

Tubercular germs are entirely eradicated from the lungs, glands or joints in four to twelve weeks, according to the stage of the disease, without any radical change in the mode of life.

The breadwinner need not abandon his employment.

The housewife need not leave her cares to others.

The student need not abandon his books.

The expensive sanatorium treatment during months or years is no longer necessary.

No more years of waiting the development of a probably fatal disease, one day on the mountain top of hope and the next in the deepest valley of despair.

No more looking forward into the grave while the inevitable end is gradually approaching.

While the patient is breathing the atmosphere, receiving the care and enjoying the surroundings of home, in four to twelve weeks at a cost of five to twenty dollars. B. & M. External Remedy puts the once conquering enemy to rout, restores the health and robs the grave of its prey.

1

Photographic reproduction (reduced) of the first page of one of the earlier "B. & M." booklets published at a time when Rollins had not developed the caution he now exhibits.

Two opinions expressed by the court in his instructions to the jury may be counted on to have a profound influence in the interests of public health and safety. The judge declared that a grave responsibility rests on the shoulders of the manufacturers of medicinal products and he quoted a pronouncement of the United States Supreme Court that persons who make or deal in products alleged to have curative powers are in a position to have, and are expected to have, superior knowledge in connection with the preparation and marketing of such articles. Judge Chesnut also emphasized that merely because a manufacturer asserts his belief in the virtues of his product, that is not to be construed as proof of good faith when the opinion of the manufacturer is opposed by overwhelming reputable medical testimony to the contrary. Rollins had access to reputable medical opinion in the manufacture and testing of his liniment, but had made no use of it. It is true that he claimed to have paid the Pease Laboratories $15,000 for the work already referred to, and he also testified that he had paid as much as $80,000 to some individuals connected with the Long Island Hospital who were alleged to have assured him by voluminous reports that B. & M. would do the things claimed for it.

That department of the government which is entrusted with the difficult duty of protecting the public from adulterated or misbranded drug products deserves great credit for the thorough and exhaustive way in which it prepared its prosecution of this case. The case itself was a crucial one in the history of the Food and Drugs Act. Upon the decision largely hinged the continued enforcement of the Sherley Amendment. No doubt the forces of evil in the proprietary medicine field have followed the B. & M. case with an interest that has been more than academic. Especial credit in the work of preparing the voluminous evidence is due to Drs. F. J. Cullen and C. E. Holton and Mr. George P. Larrick, all of the Food and Drug Administration, and to Messrs. J. F. Moore and J. B. O'Donnell of the Solicitor's office. Of course, back of all of this work lay the untiring efforts of Mr. W. G. Campbell, Director of Regulatory Work of the United States Department of Agriculture.

The two outstanding features of this case—as viewed by any intelligent student of the American scene—are these: First, the fact that it has been possible for years to sell broadcast to a particularly unfortunate group—the tuberculous—a fantastic fraud that does not have even the plausibility of ignorance in its favor. Yet it was necessary for a department of the United States government to spend thousands of dollars and expend untold effort, to say nothing of the enlisting of the help of many of the leading medical scientists of the country, to get a legal decision that B. & M. is a fraud. Second, is the astounding spectacle of a Fellow of the American Medical Association selling his services to the exploiters of what, to a physician with any knowledge of medicine, is a self-evident fraud; and selling such services for the purpose of enabling the exploiters of this wretched nostrum to continue to do business. And, greatest irony of all, for more than a quarter of a century the American Medical Association has been the one, and practically only, agency that, year in and year out, has endeavored to protect the public against just such frauds as B. & M.

Correspondence

"VITAMIN DEFICIENCIES AND NERVOUS SYSTEM LESIONS"

To the Editor:—In the editorial on "Vitamin Deficiencies and Nervous System Lesions," July 9, you quote an article of ours as attributing softenings in the cerebellum of chicks to a lack of vitamin E. Reference to our papers "A Cerebellar Disorder in Chicks, Apparently of Nutritional Origin" (*J. Exper. Med.* **53**:11 [Jan.] 1931) and "Nutritional Encephalomalacia in Chicks" (Transactions of the American Society for Experimental Pathology, April, 1931, *Arch. Path.* **12**:134 [July] 1931) will show that we have not ascribed these cerebral degenerations to a lack of vitamin E. The statement in the editorial may have been quoted from the article of Zimmerman and Burack (*Arch. Path.* **13**:229 [Feb.] 1932). These authors erroneously cite us as attributing these lesions to a lack of vitamin E.

Although the exact factor in the production of nutritional encephalomalacia of chicks has not been worked out, we have abundant unpublished evidence that wheat germ oil and other rich sources of vitamin E do not protect against the disease. Our experiments also exclude vitamin G as a possible factor.

DIAGNOSTIC SIGN FOR PLEURAL FLUID

To the Editor:—I am not aware that the following sign for the detection of fluid in the pleural sacs has been described heretofore, nor can I find any reference of it in standard works on physical diagnosis or in other medical treatises. In my hands it has proved to be a rapid, easy and useful sign by which to determine the presence of fluid of sufficient amount to be detected by ordinary methods of percussion.

Nellis B. Foster wrote: "Physical signs over fluid are variable to an extreme, and there is no combination of them which invariably indicates fluid."

If the abdominal cavity contains fluid (over 800 cc.), simple tapping of one flank with the fingers will produce vibrations or succussions on the opposite side to the palpating fingers of the other hand. This procedure is as old as any other in physical diagnosis.

If the fluid in the pleural sac is above a trifling amount (400 cc.), percussing the area over it posteriorly with the slightly flexed fingers will cause repercussions or vibrations to be felt easily by the fingers of the other hand pressed against the lumbar muscles on the same side, about the level of the third lumbar vertebra. If both sacs contain fluid, waves produced on one side will not be transmitted to the other side. They will not cross the mediastinum. If the sac on one side is so distended with fluid that it is pushed over to the other side of the spine, producing the paravertebral triangle of dulness (Grocco's sign) percussing the fluid on the suspected side will produce vibrations in the triangular area. If the chest wall is bulged by an excess of fluid, the phenomenon is more marked because of the increased tension of the liquid, and repercussions will be detected like those felt on a drum head.

In case of consolidation, as in pneumonia, without the effusion of fluid, percussion over the posterior walls of the chest (over the area of dulness) will not bring about these vibrations. The test seems to be a good differential sign between liquid and consolidated lung. The test must be performed with the patient sitting upright in order that the dependent fluid may be spread over the diaphragm. In examining patients with fluid in the pleura above the width of four ribs, I found my observations in twenty cases confirmed by aspiration or roentgen examination as well as other well known signs.

The weight of the fluid in the pleural sac has much to do with the tension of the diaphragm, sitting upright increases this because the fluid is distributed widely over the diaphragm. These vibrations felt over the quadratus lumborum are sharp, rapid in the presence of fluid and constitute a marked tremor. This weighted diaphragm, if the patient is sitting upright and leaning forward, will produce vibrations in the quadratus of the opposite side, because, very often the collection of fluid is so massive that the diaphragm, so vibrating, excites both quadrati. From the diaphragm the vibrations are transmitted to the last rib, one of its insertions is to this member, through the arcuate ligaments. The upper insertion of the quadratus is to the last rib. This muscle is without doubt an accessory muscle of respiration. If the reader will but feel his quadratus muscle he will mark it contracts violently when he coughs hard. It serves as a fixator to the diaphragm and can be looked upon as an extension of this member outside of the torso. Upon these anatomical facts the method depends. The erector spinae muscle in the thorax, if percussed, will often excite contractions in its lumbar portion; these contractions must not be confused with the vibratory tremor induced by percussed fluid. The quadratus is made tense if the patient leans forward, it does not contract but vibrates when the chest is percussed. Leaning forward puts this muscle on the stretch, increases its tonus to the tension of a bow string. This position is important. A stretched piece of parchment would vibrate if it was in the place of the muscle. In heavily muscled men, sometimes the quadratus will exhibit slow heavy waves when the chest is palpated under the above conditions. Palpating the quadratus when the chest is percussed in the presence of fluid is the best way to distinguish these two kinds of vibratory phenomena. The waves are probably magnified in the quadratus because the long diaphragm and quadratus make leverage effect when the chest is percussed. The last rib serves as fulcrum. Then, too, hydraulic phenomena have much to do with the magnification.

The upper level of the fluid may be determined by this method. If one percusses over fluid beginning at the top percussing downward, and palpating the muscle at the same time, the vibrations will begin to be felt when this level is reached. This method seems to be reliable in denoting this. With a cannula in the chest fluid proving its presence, I found that by lowering the level from a previously determined top by evacuating 30 cc. the fluid diminished the width of two vertebrae, noted again by percussing the chest and palpating the quadratus. The method not only will locate the extent of the effusion but will detect it as well. In this case the film of fluid between the ribs and the lung must have been very thin, because 30 cc. covered the entire width of the lung. It appears from this observation that the method will prove the presence of very small amounts of fluid.

Robert L. Pitfield, M.D., Germantown, Pa.

Queries and Minor Notes

SKIN GRAFTING AFTER BURN

To the Editor:—I have a patient who was badly burned in January as the result of an attendant's carelessness in applying an electric pad to her paralyzed right leg. The skin has healed, but there is still an exposed surface of the tibia measuring about 1½ inches by 1 inch. The periosteum was destroyed in this area by the burn, but the exposed bone appears perfectly healthy. The open area is undoubtedly growing smaller, but at such a slow rate that it may take another year for it to close up. I can find no information in my own library concerning the best method of treatment. Will you please tell me what is now considered the best way to treat this condition?

J. L. Rains, M.D., Seattle.

Answer.—Lesions of the leg tend to heal slowly, especially when the circulation is impaired by a paralysis. Conservative methods are probably useless, although the ulcer area might be kept covered with narrow strips of adhesive plaster, changed every three or four days. If no healing should result within a few weeks, operation would be indicated. If there is a layer of granulation tissue, it should be freshened with a knife or a curet and Thiersch grafts put on. If the surface of the bone is present in the wound there is probably a thin cortical sequestrum of dead bone. This should be chiseled off and, after granulations have formed, Thiersch grafts may be placed on this area. This might heal under adhesive strapping, although it is preferable to cover such areas with skin grafts.

ENDAMEBA COUNCILMANIA LAFLEURI

To the Editor:—In Todd and Sanford's "Clinical Diagnosis by Laboratory Methods," edition 6, page 57, section 5, in the paragraph heading "Other Endamebae," the following statement is made: "Under the name Councilmania lafleuri, Kofoid and Swezy recently described an exceptionally actively motile endameba which ingests red blood corpuscles and is probably pathogenic. Its cysts are very thick walled, ovoid, 16 to 20 microns in diameter, and contain eight nuclei. It is not accepted by all protozoologists." Will you please inform me as to the present status and pathogenicity of this organism? Please omit name.

M.D., New Mexico.

Answer.—In 1921, Kofoid and Swezy described Councilmania lafleuri as a new ameba of the human intestine (University of California Publications on Zoology **20:**169). In 1922 Gunn (*J. Parasitology* **9:**24 [Sept.] 1922) recounted studies which he felt disproved the assertion that this form was actually new. In 1924, Kofoid, Swezy and Kessel (University of California Publications on Zoology **26:**21) gave further data in support of their view. In April, 1926, Wenyon discussed the question in extenso in his monograph on Protozoology (p. 221) and concluded thus: "The writer still believes that there is no justification for the genus Councilmania and that the characters which distinguish C. lafleuri from Endamoeba coli fall within the range of variation of E. coli itself." Several brief papers since that date have offered support for each side of the question, but no thorough study has been made. In Problems and Methods of Research in Protozoology by Hegner and Andrews (New York, Macmillan Company, 1930), the problem is not even mentioned. One contributor uses the name, another avoids using it. The question is certainly still *sub judice.* Until further evidence is secured, both the name and its rôle in the human body cannot be settled.

PERSISTENT FURUNCULOSIS

To the Editor:—I have under my care a woman, aged 33, who has suffered from furunculosis for the past seven months. The past history, except for iridocyclitis in the left eye twenty years ago, is negative. About thirteen months ago she gave birth to a normal girl and was nursing the child for nine months. It happened during the last lactating months that she developed the furunculosis, especially on the trunk under the breasts and on the lower extremities. The face and neck were spared. The furuncles developed into considerable sized abscesses, painful, discharging thick but not abundant pus, and leaving disfiguring scars. There are usually two abscesses appearing at the same time. Her physical condition is negative. During the onset of the furunculosis she was overweight, but she has lost considerable weight since and become anemic, the hemoglobin being 68 per cent. The urine shows a slight trace of sugar. The blood sugar (65 mg. per hundred cubic centimeters) and chemistry are normal. The Wassermann reaction is negative. Blood culture did not reveal any abnormality. I tried vaccine, foreign protein treatment, roborant tonic, sulphonated bitumen ointments, sulphur baths, ultraviolet rays, dietetic treatment to eliminate the traces of sugar (lactose), and arsenic (solarson) injections. Liver therapy is being tried to increase the hemoglobin and improve the secondary anemia. But there seems not to be any sign of abatement of this condition. Please suggest any further treatment. Do you approve injections of the patient's own blood? Please omit name and address.

M.D., New York.

Answer.—Evidently this case of furunculosis presents unusual difficulties. The measures previously instituted will usually control an ordinary furunculosis. Since the patient's general physical condition is satisfactory, the persistence of the eruption cannot readily be explained on the basis of a debilitating systemic disease. The subsequent development of abscesses with disfiguring scarring suggests skin lesions other than ordinary furuncles. If it has not been done, studies by smear, culture, and animal inoculation should be made for the bacillus of tuberculosis and the mycotic infections. It is possible that a biopsy might clinch the diagnosis. If the lesions are, however, the ordinary furuncles, the patient should be carefully instructed not to manipulate them. Sulphur baths and small doses of foreign protein should be continued over a considerable period. There can be no objection to giving four or five injections of the patient's own blood parenterally. The carbohydrate intake should be kept at a low level.

PRURITUS IN DIABETIC PATIENT

To the Editor:—I have a diabetic patient, aged 63, who is suffering from intractable generalized itching of the skin. The diabetes is well controlled by diet and insulin, so that sugar appears in the urine only occasionally. I have tried various lotions with only temporary relief. He sleeps fairly well, and during the night the itching subsides somewhat. Sedatives have been tried but do little good. At present I am giving him calcium gluconate, 20 grains (1.3 Gm.) daily. Can you suggest any treatment that might give more or less permanent relief? Please omit name and address.

M.D., Illinois.

Answer.—Generalized itching of the skin in elderly persons with diabetes is comparatively rare and is sometimes exceedingly difficult to control. As far as treatment is concerned, the usual procedures, such as calamine lotion, keeping the skin well oiled, may be of no avail, in which case therapeutic x-rays may be tried. There are two suggestions that may be made: (1) to see whether the treatment of the patient with a lower diet and no insulin might be of some effect, and (2) to have a basal metabolism test done. If the test shows a minus rate, thyroid in therapeutic doses at times alleviates itching.

POTASSIUM SALTS AS CARDIAC REGULATOR

To the Editor:—Kindly note the following newspaper clipping about potassium salts as a cardiac regulator, reported by Dr. John J. Sampson at the A. M. A. Session in New Orleans: "Certain potassium salts correct irregular heart beats and slow down too rapid heart action, according to John J. Sampson, M.D., of San Francisco. He said it is found this form of potassium can be taken safely by mouth. Its effects begin in thirty to fifty minutes, and last six to eight hours." I should like to get the preparation and the dose.

H. J. Friedman, M.D., San Antonio, Texas.

Answer.—Doses of from 2 to 4 Gm. of potassium acetate, in 25 per cent aqueous solution, were given every six to eight hours.

PERSISTENT URTICARIA

To the Editor:—I am being tormented by a persistent urticaria, at times and locations with the usual wheals, when scratched, but also with widespread local pruritus, chiefly at night. Frequently I pass most of the day in comfort, with occasional local irritation. I have checked up all skin tests for every food used, none giving a positive reaction. But anyway, I have for a week at a time eliminated from my diet anything that I thought might be at fault — milk, wheat, eggs, sugar. There is not a trace of sugar in the urine, and the sugar in the blood is about normal. I have taken a good saline purgative, with subsequent restriction of diet to fruits and vegetables and alkalis to the point of neutralizing the urine. I have checked up all possible sources of local irritation, such as bath and laundry soaps and bathroom powder, even leaving off my daily bath for a week. I am 65 years old, 150 pounds (68 Kg.) in weight, and I think, a normal human being. I have plenty of outdoor interests and exercises, am of regular habits, use no tobacco or stimulants, sleep on an open porch, go to bed at nine, arise at six, and do nothing to which I could judge that a nervous element could be contributing. If you can suggest anything it would be most gratefully received. I have just noticed an abstract in The Journal of May 7, page 1692. Could you say anything along this line? If so, kindly designate method and dosage for use and where the sodium dehydrocholate is obtainable. Please omit name and city.

M.D., Louisiana.

Answer.—The treatment of chronic urticaria has not been as satisfactory as that of bronchial asthma and hay fever, yet good results are frequently obtained. The condition is usually due to a food, but some cases are caused by contact with something that irritates the patient. This may be some substance such as silk or wool or something in the bedroom; e. g., a hair mattress or a feather pillow. These factors should be thought of and removed. Protein sensitization tests coupled with food elimination diets are often successful in pointing out the cause. If all these fail, and they often do, one resorts to nonspecific methods of treatment. One of these is the use of bile salts. No doubt all bile salts act more or less similarly. Sodium choleate (sodium choleinate), Merck, is dried purified ox-gall; it is claimed to contain, for the most part, sodium salts of glycocholic and taurocholic acids, along with some cholesterol, choline and lecithin. The dosage is from 0.3 to 0.6 Gm. (5 to 10 grains). Sodium dehydrocholate is marketed as Decholin Sodium (New and Nonofficial Remedies, The Journal, March 12, p. 887).

REACTION TO DRUGS

To the Editor:—A patient who has influenza with coryza has taken acetylsalicylic acid for one day, beginning the following day with a different brand, in the usual dosage, for three days. An added cold was taken and the patient then took amidopyrine for several days, one tablet every four hours, or one 5-grain tablet every four, six or eight hours as symptoms indicated. After about four days a papular rash appeared on the flexor surfaces of the arms and back, somewhat on the abdomen, legs, neck and chest, and somewhat less on the back, arms and legs. Itching was not so noticeable at first as it was after a day or so. The patient also was taking a nasal spray of ephedrine (Swan-Myers Company). It developed that a sinus condition was present that was not draining well. All medicines have been stopped. Elimination, bowels, skin and kidneys are all active, with fluid increased. The patient cannot sleep. Just what may be given safely in order not to increase the skin irritation and to induce sleep? Please omit name.

M.D., Iowa.

Answer.—In case the eruption described is due to one of the medicines that he has been employing, it is probable that the patient would be able to take any of the standard sedatives without danger of increasing the eruption, since the sensitivity may exist for only a single drug. In case the eruption seemed to be increased on taking one of these synthetic sedatives, this should be discontinued and bromides might be employed. It is impossible to suggest any single agent to which some individuals might not react.

PYELITIS AFTER OTITIS MEDIA

To the Editor:—What would you consider the best treatment in the following cases: About twelve weeks ago I did a paracentesis in four cases of acute purulent otitis media in children between the ages of 8 and 10. They all presented pyelitis with numerous pus cells and some erythrocytes, a few hyaline and granular casts, and acid reaction. The ear conditions cleared up entirely, but in all cases the urine remained unchanged despite protein and salt-free diet, general care, ultraviolet irradiations and ingestions of Pyridium. Please omit name.

M.D., New York.

Answer.—The most important thing is to determine whether the children are suffering from a pyuria of bacterial origin or whether they are still suffering from a postinfectious hemorrhagic nephritis. A culture of the catheterized urine will rule out the former and a careful examination of the urinary sediment as well as tests for albumin and examination of the blood urea will determine the latter. The treatment will depend on the diagnosis. If a pyelitis, the administration of methenamine after acidifying the urine with ammonium chloride, 1 Gm. four times a day, should clear up the infection rapidly if there is no urinary anomaly. Treatment of the nephritis will depend on the condition found. Pyridium has not been established as useful in infections of the urinary tract.

MULBERRY TREE AS SOURCE OF SENSITIZATION

To the Editor:—Can you inform me or direct me where I can find out whether mulberry trees are poisonous: leaves, bark or roots of the black and white mulberry trees? What I should like to know is whether they could poison by direct contact or produce an allergy resulting in an allergic dermatitis. There is no mention made of this in any of my books, and my druggist says that his books do not mention that they are poisonous.

H. W. Eby, M.D., Goshen, Ind.

Answer.—A search of the literature failed to reveal any mention of skin trouble from contact with mulberry trees. There are listed ten species of mulberry trees (Morus), four of which occur in the United States. The paper mulberry (Papyrius papyrifera Kuntze) has recently been definitely shown by Bernton (*J. Lab. & Clin. Med.* **13**:829 [June] 1928) and by Balyeat and Rinkel (*J. Allergy* **3**:7 [Nov.] 1931) to be an important cause of hay fever and asthma. It pollenates is April and May and it is a common tree in the eastern and southern parts of the United States. Its pollen is highly toxic. From what is known of other pollen, such as ragweed and grass, the pollen of the paper mulberry tree might well cause skin disease.

STATISTICS OF DISEASES OF THE EYE

To the Editor:—I am anxious to get statistics as to the percentage of people in the United States who have squint, progressive myopia and glaucoma. Have you this information available, or do you know where I might be able to get it?

Gordon H. Gliddon, Hanover, N. H.

Answer.—There are no statistics available to answer these questions. Statistics from some of the various well organized clinics as well as statistics from private practice can show the percentage of squint, progressive myopia and glaucoma as they occur among the patients who visit that clinic or private practice; but this bears no relationship to the population as a whole. Even in a country as statistically minded as is Germany, such figures are mostly guesswork.

PUPILLARY REACTIONS IN PERNICIOUS ANEMIA

To the Editor:—Does paralysis to both light and in accommodation of the eyes occur in pernicious anemia? I can find where optic atrophy and hemorrhages into the retina occur, but no mention of the loss of the reflexes mentioned.

J. D. Butzner, M.D., Scranton, Pa.

Answer.—In a few cases of pernicious anemia, the pupils have been found to be moderately dilated, although reacting promptly to light and in accommodation. As far as can be found from a search of the literature no specific pupillary paresis has been described, although in some cases there have been pupillary disturbances secondary to the extensive hemorrhages in the retina and optic nerve. As a rule the main ocular changes in pernicious anemia are to be found in the background of the eyes.

RECTAL ETHER ANESTHESIA

To the Editor:—In Queries and Minor Notes (The Journal, May 28) the question is asked whether "rectal ether anesthesia (Gwathmey method) is contraindicated in infections of the respiratory tract because of the danger of ether pneumonia during the period of elimination." This question is rightly but not completely answered as it might be when it is stated that there is doubt whether it is sufficiently concentrated in rectal analgesia to affect the lungs. The amount usually given in rectal anesthesia is 2½ ounces (75 cc.) of ether. It escapes from the lungs at the rate of 1¼ drachms (4.65 cc.) every five minutes. It is moistened and warmed by the time it reaches the lung. I have never known of a pneumonia to follow ether when given by rectum, in three or four times the amount given in obstetric cases.

A few years ago, in association with other physicians, I gave a tuberculous patient 2 ounces (60 cc.) of ether and 1 ounce (30 cc.) of oil by rectum three times a week for more than four months with the hopes of affecting his disease favorably. While the patient stated that he felt better after each treatment, his chart showed no improvement in any way, and the method was abandoned. Later I gave by rectum to a patient with an enlarged tongue 5 ounces (150 cc.) of ether and 2½ ounces (75 cc.) of oil for the surgical removal of the obstruction. The patient's sputum was changed from a positive to a negative culture, but unfortunately he disappeared from the hospital as soon as his tongue was healed. There are references in medical literature for a theoretical basis for the treatment of tuberculosis of the lung by ether. From a large clinical experience, I can state positively that ether is not contraindicated in obstetric cases when given by rectum, regardless of whether the lesion is active or quiescent.

All authorities are agreed that ether is contraindicated by inhalation in any stage of tuberculosis.

James T. Gwathmey, M.D., New York.

Council on Medical Education and Hospitals

COMING EXAMINATIONS

American Board for Ophthalmic Examinations: Montreal, Sept. 19. Sec., Dr. William H. Wilder, 122 S. Michigan Ave., Chicago.

American Board of Obstetrics and Gynecology: The examination will be held in nineteen different cities in the United States and Canada, Oct. 22. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh.

American Board of Otolaryngology: Montreal, Sept. 17. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

California: *Reciprocity.* Los Angeles and San Francisco, Sept. 21. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

National Board of Medical Examiners: The examinations in Parts I and II will be held at all centers where there are five or more candidates available in a Class A medical school, Sept. 14-16. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

New Hampshire: Concord, Sept. 8-9. Sec., Dr. Charles Duncan, Concord.

New York: Albany, Buffalo, New York and Syracuse, Sept. 19-22. Chief, Professional Examinations Bureau, Mr. Herbert J. Hamilton, 315 State Education Bldg., Albany.

Oklahoma: Oklahoma City, Sept. 13-14. Sec., Dr. J. M. Byrum, Shawnee.

Porto Rico: San Juan, Sept. 6. Sec., Dr. O. Costa Mandry, Hospital Mimiya, Santurce, San Juan.

Wisconsin: *Reciprocity.* Milwaukee, Sept. 13. Sec., Dr. Robert E. Flynn, 315 State Bank Bldg., LaCrosse.

Connecticut March Report

Dr. Thomas P. Murdock, secretary, Connecticut Medical Examining Board, reports the written examination held in Hartford, March 8-9, 1932. The examination covered 9 subjects and included 70 questions. An average of 75 per cent was required to pass. Sixteen candidates were examined, 13 of whom passed and 3 failed. Eleven physicians were licensed by endorsement. The following colleges were represented:

College PASSED	Year Grad.	Per Cent
Yale University School [illegible]	[illegible]	84.9
Georgetown University [illegible]	[illegible]	75, 75.5

Book Notices

Surgical Pathology of Prostatic Obstructions. By Alexander Randall, M.A., M.D., *Professor of Urology, University of Pennsylvania.* Cloth. Price, $7. Pp. 266, with 100 illustrations. Baltimore: Williams & Wilkins Company, 1931.

This book represents an analysis of various types of gross prostatic pathologic changes extending over a period of ten years at the Philadelphia General Hospital. Out of a total of 1,215 necropsies, 312 cases, or 25.6 per cent, of gross pathologic changes were found, of which 65 per cent were in white persons and 35 per cent in Negroes. Since numerous investigators have contributed much toward the microscopic side of prostatic pathology, in this treatise the author had only the questionable specimens studied microscopically. Hypertrophy, median bar, carcinoma and abscess were especially studied in regard to their incidence, characteristics, relation to age, clinical conditions, race, and the best type of surgical procedure to be carried out. The book is divided into six chapters. The illustrations show the various characteristic types of prostatic pathologic lesions. Benign prostatic hypertrophy was found to be the most common lesion, with true fibrous median bar second, while carcinoma and abscess were less common. The first part of the book shows the incidence of the different types of prostatic disease. Each lesion is illustrated by plates showing the different gradations of each type with a history of the case followed by a gross pathologic description. Results of microscopic examination were included when there was any doubt as to the diagnosis. Evidence of a malignant condition appeared in 7.1 per cent of the entire study, and in the majority both lateral lobes were involved while the posterior lobe remained free. This is important, as the general belief is that the posterior lobe is most commonly involved first in carcinoma of the prostate.

The book, with its histories of the cases presented, the discussion, and the charts and plates, gives the urologist a work of unprecedented value.

Initiation aux examens courants de la gorge, du nez et des oreilles. Par Henri-Pierre Chatellier, oto-rhino-laryngologiste des Hôpitaux de Paris. Préface de L. Baldenweck. Paper. Price, 50 francs. Pp. 323, with 152 illustrations. Paris: Masson & Cie, 1932.

After some general advice regarding the proper attitude toward patients, the author suggests some principles of examination of the throat and the larynx. With reference to the latter, the various types of indirect as well as direct methods are discussed. This is followed by two chapters on rhinoscopy both anterior and posterior. Considerable attention is given to the examination of the sinuses and the method of puncturing the antrum of Highmore. Examination of and methods of inflation of the eustachian tube are the subjects next discussed. This is followed by a general description of the methods of examination of the ear, with reference in particular to the external parts. The function of the internal ear is then discussed from the standpoint of the examination of audition, followed by vestibular tests. The usual tuning fork tests are mentioned as well as the use of the monochord. Examination of the vestibular apparatus is entered into with considerable detail. Throughout the work the author is careful to call attention to the exact technic that is used in the examination and shows by means of illustrations drawn by himself the anatomy of the various parts described and the method of manipulating the patient in making the various tests. The work will be of definite value to the advanced student in medical schools, the general practitioner who has to make some of the elementary examination of the ear, nose and throat, and last, but not least, the man about to take up the specialty of otolaryngology.

Directory of Psychiatric Clinics in the United States. Compiled and edited by the Division on Community Clinics of the National Committee for Mental Hygiene. Paper. Price, $1. Pp. 165. New York: Commonwealth Fund, 1932.

The growth of the child guidance movement is clearly indicated by a comparison of this volume with the earlier editions published in 1925 and 1928. The number of clinics listed is:

1925	318
1928	492
1931	674

The great increase during the last three year interval is due in part to the inclusion of psychiatric clinics for adults in the latest edition; but as there are only fifty in this group, the net increase of clinics serving children is approximately 130. Of the 674 clinics in the country, 232, just over a third, provide the complete service of psychiatrist, psychologist and psychiatric social worker. The new edition, which is believed to be complete, represents a canvass of the entire country. Not only psychiatric clinics but also neurologic clinics, so called, were included when they were found to offer, in reality, psychiatric service. No attempt has been made to evaluate the clinics, but the directory indicates clearly the type of organization and the scope of each.

Thérapeutique médicale. III: Foie, glandes endocrines et nutrition. Par Maurice Loeper, professeur de thérapeutique à la Faculté de médecine de Paris. Avec la collaboration du Dr. André Lemaire, chef de laboratoire à la Faculté. Paper. Price, 50 francs. Pp. 377, with 58 illustrations. Paris: Masson & Cie, 1931.

The French physician needs no therapeutic consultant. Apparently his library must keep freshly littered with the simply amazing number of therapeutic monographs on every subject and subhead foisted on their medical fraternity in a continuous outpouring. Every volume advertises a future series. One must shruggingly conclude that these postgraduate manuals fill the need of the French practitioner; otherwise, the publisher would find no market. This volume of a series on medical therapeutics treats of nutrition generally and of disorders of the liver and endocrine glands. It includes chapters on gout, obesity, chronic rheumatism, phosphorus, calcium and vitamins, and a concluding chapter on urinary excretion. Nothing is taken for granted. Predigestibility, simplicity and availability of the contents are served by a detailed summary at the beginning and a list of prescriptions at the end of each chapter. Schematic histology and graphs illustrating the mode of drug action add to the clarity of the book. The material is concise and represents a practical summary. The chapter on general physiology of digestion is especially interesting. The author scores in medical literature by referring to the glands of internal secretion as the carburetors of the body economy. It may be too critical to indicate that some recent developments in this field have not been emphasized; namely, cortin, the rôle of the female sex hormone in the treatment of hemophilia, and the effect of pituitary extracts on the growth of hair.

A Study of Dental Clinics in the United States: 1930. By Miriam Simons Leuck, of the Research Staff of the Committee on the Study of Dental Practice of the American Dental Association. Statistical Adviser: Charles A. R. Wardwell, Assistant Professor of Statistics and Finance, Northwestern University. Publications of the Committee on the Study of Dental Practice of the American Dental Association, No. 3. Paper. Pp. 107. Chicago: University of Chicago Press, 1932.

Various studies have been made of dental clinics and their relations to specific localities or individual clinics, but it appears that this study is the first attempt to assemble widespread information. Under the study are included such topics as the number of clinics, their geographic distribution, number of patients served, number of visits made by patients to clinics, the amount of fundamental equipment devoted to clinic work, and the number of dentists engaged in this type of service. There is found also a classification of the types of clientele served. Of considerable importance in understanding the scope of interest in dental care that has spread outside the dental profession is an enumeration and discussion of the agencies that direct dental clinics.

In this study, reports were made on 1,530 clinics. This number included at least one from every state in the United States, with an average of over two clinics for each city reporting. In 1930 the reports showed that at least 1,962,791 patients were treated in dental clinics. The extent of dental clinic service is further shown by the fact that 3,314 chairs are reported as being devoted to this service. It was stated that 28 individuals out of every 1,000 living in cities received dental clinic treatment during 1930, the year covered by the study. The smallest of these clinics served only 4 to 10 patients during the year, but several reported an attendance of over 75,000 patients and one clinic reported a service to 110,000 in 1930.

The relative importance of the different classes of agencies conducting dental clinics is shown by the following figures: The number of clinics conducted by local and county governments is 469; by hospitals, 378; by federal and state governments, 270; by lay and charitable organizations, 200; by dental schools and societies, 137; and by industries and business firms, 76. Information is not complete on the number of dentists connected with the full number of 1,530 clinics reporting; however, some 400 or more clinics volunteered information on this point. In these clinics there were reported 207 full time dentists, 515 part time dentists, and 11 dental interns. Almost half of the clinics (48 per cent) confined their work exclusively to children. Over 16 per cent reported that their service was maintained for adults only, while over 33 per cent maintained a service for both adults and children. The patients, classified according to age, consisted of 1,006,918, or over 62 per cent, children and 596,956, or more than 37 per cent, of adults. It was impossible in the study to make a detailed analysis of the services rendered, the class of patients admitted, charges made and the salaries paid the operator. These items, together with the social problems involved, are to be presented in a report of a further study.

The study is accompanied by a number of significant tables in both the text and the appendixes. Although it appears that the author anticipates a more extensive report, the material presented is sufficient to show that there exists in the United States today a widespread interest in dental clinics both among the members of the dental profession and among organizations interested in public health. There is likewise an evidence of interest on the part of the public, which is shown by the extent to which these clinic facilities have been utilized.

Pathologie und Therapie der Erkrankungen des Kehlkopfes, der Luftröhre und der Bronchien. Von Prof. Dr. M. Hajek, Vorstand der Universitätsklinik für Kehlkopf-, Nasen- und Ohrenkrankheiten in Wien. Abteilung 1. Paper. Price, 53 marks. Pp. 192, with illustrations. Leipzig: Curt Kabitzsch, 1932.

This is the first section of what promises to be a complete treatise on the pathology and treatment of the diseases of the larynx, trachea and bronchial system, and it deals with these subjects in a beautiful manner. In the first chapter, the anatomy of the larynx, trachea and bronchial tubes is discussed, followed by the second chapter on the physiology of the larynx and airways. The third chapter deals with the various methods of indirect and direct examination (endoscopy), with much attention to the proper instrumentation. The fourth chapter presents the pathology of the upper air passages, including anemia, acute and chronic catarrhal inflammation of the laryngeal, tracheal and faucial mucosa, laryngeal edema, acute laryngitis and perichondritis. There is a good discussion of some of the acute infectious diseases which involve the larynx and the air passages, including such diseases as scarlatina, measles, smallpox and diphtheria. The volume ends abruptly in the middle of a sentence in the portion in which diphtheria is being discussed. It is hoped that the other two sections of this subject will soon appear, so that the complete story can be presented. The part thus far published is well illustrated with black as well as colored drawings and figures. This work should prove most valuable to the library of the laryngologist, especially to the man interested in endoscopy in all its phases.

A Practice of Medicine. By Prof. Adolf Strümpell. Volume I: Infectious Diseases. Diseases of the Respiratory and Circulatory Systems. Volume II: Diseases of the Digestive and Urinary Systems. Diseases of the Organs of Motion. Diseases of Metabolism. Volume III: Diseases of the Nervous System. Authorised translation from the thirtieth German edition by C. F. Marshall, M.Sc., M.D., F.R.C.S., and C. M. Ottley, M.A., B.M., F.R.C.S. Twenty-ninth and thirtieth editions by E. Seyfarth, D.Med. et Phil., Professor of Medicine at the University of Leipzig. Fabrikoid. Price, $33 per set. Pp. 2356, with 392 illustrations. Philadelphia: F. A. Davis Company, 1931.

Since this work was first published, in 1883, it has been in constant demand and has been translanted into seven different languages. At the death of the author, in 1925, Professor Seyfarth of Leipzig undertook the revision of the book. He has maintained the original arrangement of the text as well as the emphasis on the clinical aspect of disease. Strümpell was prominent as a clinician and throughout his previous editions he emphasized the importance of clinical study and observation and the correlation of external symptoms with internal pathologic conditions. In this edition Dr. Seyfarth has attempted to maintain the ideals of Strümpell and has not overstepped the limits of a practical textbook of medicine. Many new therapeutic and diagnostic measures have been introduced since the last edition of the book, but the author has included only those which he himself has tested and found useful. The first volume consists of chapters on the acute infectious diseases, special infectious diseases, and diseases of the cardiovascular and respiratory systems. In keeping with the thought expressed by the author in the preface, he has not included any form of treatment unless its usefulness has been firmly established. The definite success that has attended the use of diphtheria toxoid in the prophylaxis of diphtheria merits more than casual mention, however. In the chapters on diseases of the respiratory and cardiovascular system, the clinical aspect is clearly and concisely .correlated with the underlying pathologic condition wherever possible. The second volume is devoted to diseases of the digestive and urinary systems, blood, endocrine glands and disorders of metabolism. Before discussing the subject of nephritis, the author has included a general discussion on renal disease in an effort to clarify some of the points which tend to make this subject confusing to the general practitioner. The chapter on blood is unusually complete for a treatise of this type. The third volume deals with the diseases of the brain and nervous system. This part of the work is excellent. The subjects are covered with almost the same thoroughness as in a textbook on neurology, and yet the facts are concise and readily available to those who are not specially trained in diseases of the nervous system. The general practitioner will find these volumes a reliable and conservative textbook of medicine. The style of the book is of such nature that it will serve as a readily available source of practical clinical information and a guide to the peculiarities of individual cases.

Über das elektrische Schneiden mit der Drahtschlinge in der operativen Dermatotherapie und kleinen Chirurgie unter besonderer Berücksichtigung der Hauttuberkulose. Von Dr. med. Vinzenz Wucherpfennig, Priv.-Doz., Ass.-Arzt der Univ.-Haut-klinik Münster (Westf.). Mit einem Geleitwort von Professor Dr. A. Stühmer, Direktor der Univ.-Hautklinik Münster (Westf.). Paper. Price, 7 marks. Pp. 84, with 82 illustrations. Jena: Gustav Fischer, 1932.

This is a monograph based on four years' experience with electrosurgery with the wire loop. There is an introductory chapter on the historical development of the various types of electrical cutting procedures. In the second chapter the theoretical and practical application of the cutting current is taken up in detail and three types of incisions with a specially constructed wire loop are described under the titles of "Hohlschnitt," "Flachschnitt" and "Spaltschnitt." The questions of hemostasis, anesthesia and after-treatment are adequately discussed. The author's preference is for healing of even large defects by granulation rather than by skin grafting or tissue transplantation. The main application of this method of electrosurgery is found in the field of cutaneous tuberculosis, although it is also used for biopsy, skin cancer, nevi, verruca, senile keratoses and the excision of x-ray ulcers and carcinomas. Of 654 cases treated by the author, 452 were cases of tuberculosis cutis. The cosmetic results in this disease are naturally of the greatest importance in addition to the time factor, as it is well known that the modern dietetic and actinic treatment of cutaneous tuberculosis is a slow and time-consuming procedure. A careful study of the illustrations showing the end-results of the treatment would lead one to the conclusion that this method causes an excessive amount of scarring and that the cosmetic results cannot compare with those of modern Finsen therapy. The main advantage seems to be found in the saving of time, the saving of expense and possibly a diminished frequency of recurrence in the scar tissue. It is apparent that this method of electrical surgery should not be undertaken lightly or without special training in the various methods of procedure.

The History of Paediatrics: The Progress of the Study of Diseases of Children up to the End of the XVIIIth Century. By George Frederic Still, M.A., M.D., Hon. LL.D., Professor of Diseases of Children, King's College, London. Cloth. Price, $8. Pp. 526, with illustrations. New York: Oxford University Press, 1931.

Those who are interested in pediatrics or the history of the development of this specialty will find in this volume delightful and instructive reading. It is the first work of its kind by an Englishman, and much of it is particularly devoted to the development of pediatrics in England. The material presented consists largely of thumbnail biographic sketches set forth in the author's usual delightful style. A scientific accuracy and terseness permeates the book. The subject matter is chronologically organized and spans the period from Hippocrates through the eighteenth century. A great deal of original research work has been done in collecting and assembling known and heretofore unknown data. As source material the author has liberally drawn from early inaugural dissertations. A bibliography of these in the appendix lends additional value to the book. The text is richly illustrated by well chosen reproductions of early medical editions dealing with the care and treatment of infants and children. There are also numerous reproductions of fine old portraits, all of which constitute a fairly comprehensive collection of pediatric pioneers. The biographic nature of the book recommends it as a ready reference volume. Its simplicity, continuity and charming style merit it a prominent place among the contributions to medical history.

Tuberculosis in South African Natives With Special Reference to the Disease Amongst the Mine Labourers on the Witwatersrand. Being the Report of the Tuberculosis Research Committee, Originally Established by the Transvaal Chamber of Mines and Later Expanded Into a Joint Committee by Incorporation of Representatives of the Union Government. Publications of the South African Institute for Medical Research, Volume V, No. 30. Edited by the Director. Paper. Pp. 429, with illustrations. Johannesburg: South African Institute for Medical Research, 1932.

This elaborate report will interest all who are concerned actively in the study and prevention of tuberculosis. It shows strikingly the magnitude, complexity and difficulties of the tuberculosis problem in South Africa. Here the disease flourishes in the manner more or less characteristic of its manifestations on "virgin soil." From isolated, often distant, native communities are recruited large numbers of laborers for work, mostly underground, in the mines on the Witwatersrand. Above ground the miners live in crowded and insanitary compounds. The term of the mine labor usually is one year. The number of hours underground each day is at least ten, with little or no chance for food or rest in the meantime. It is consequently no wonder that active tuberculosis develops in large numbers of the workers, most of whom carry the disease back to their home communities on repatriation after their term is over. The report describes the condition both of the mines and of the home life of the natives and offers a series of well founded and constructive recommendations for reducing the sources of infection and increasing the resistance. The lack of adequate statistics concerning the native population as a basis for assessing the value of health work is emphasized. The usefulness of the report would have been increased by an index.

Will It Be a Boy? Sex-Determination According to Superstition and to Science. By Dr. F. Økland, Assistant Professor, Aas, Norway. Cloth. Price, $1.50. Pp. 116, with 14 illustrations. New York: Century Company, 1932.

This book was written for laymen. In simple language the author explains the known facts of sex determination not only in human beings but also and in greater detail among the lower animals. The first part of the book contains a discussion of a few superstitions concerning the determination and the wilful control of the sex of offspring.

Medicolegal

Pharmacists: Liability for Quality of Drugs Sold.—A druggist, under section 5813 of Mason's Minnesota Statutes, 1927, is responsible for the quality of all drugs, chemicals and medicine sold by him, except proprietary medicines and other articles sold in the original packages of the manufacturer. In the opinion of the Supreme Court of Minnesota, this section was not enacted to relieve druggists of responsibility but was enacted for the additional protection of the public. At common law, a druggist is bound to exercise toward his patrons that degree of care which is commensurate with the hazards and dangers to which they are exposed. Only as to the quality of nonproprietary medicines has the statute undertaken to define the responsibility of the vender. In other respects and as to proprietary medicines, the law requires the same degree of care that was required at common law. In connection with the sale of proprietary medicine in original packages, the druggist is not required to analyze the medicine or drug, when sold for the purpose for which compounded, and if the manufacturer is a reputable one the druggist may rely under ordinary circumstances on the rectitude of the manufacturer and the correctness of his compound. Ordinary care under such circumstances does not require a greater degree of diligence. But when a druggist obtains from a manufacturer drugs which he does not sell under the name of the manufacturer, but under his own name, accompanied by a statement that it was manufactured or prepared for him, the druggist assumes a responsibility equivalent to that of the manufacturer of the drugs. The word "proprietary," as applied to medicines, necessarily implies that the medicine has been compounded by a manufacturer who prepared the medicine according to his own formula, though probably it is not necessary that the formula be the exclusive property of the maker or that the process be secret. A medicine cannot be considered "proprietary" unless the original package in which it is contained bears the name of the manufacturer. If it does not, it comes within the rule applied to other medicines and drugs sold by a druggist, for the quality of which the statute holds him responsible.—*Tiedje v. Haney (Minn.), 239 N. W. 611.*

Workmen's Compensation Acts: Lead Poisoning an Accident.—Ramsay was engaged in welding the edges of sheets of lead lining large tanks and cells. After having been so engaged for about four weeks, he manifested symptoms of lead poisoning. He had had no experience and had no information as to the danger of his work and did not knowingly submit himself to its hazards. His employer was equally ignorant, and if he had realized the hazards of the task, he would have furnished his employee with a respirator or mask, which he did not do. The evidence showed that the oxides of lead absorbed into the employee's body brought about a result in a few weeks which, according to the testimony of medical witnesses, would usually take a period of months or possibly years to produce and which was not the customary or natural result that follows the absorption of lead oxide into the system. In the shortness of the time within which disability resulted lies the distinction between an occupational disease and an injury by accident. If the injury was the result of lead poisoning, under the peculiar circumstances of this case, said the Supreme Court of Idaho, we are of the opinion that it was a personal injury by accident arising out of and in the course of employment, within the meaning of the workmen's compensation acts, and that it was therefore compensable.—*Ramsay v. Sullivan Mining Co. (Idaho), 6 P. (2d) 856.*

Revocation of Physician's License: Necessity for Notice of Hearing.—Before a license to practice medicine in Florida can legally be revoked, a copy of the charges on which it is proposed to take action and a notice of the time and place when and where they will be heard by the board of medical examiners must be served on the licentiate. If a license is revoked, the licentiate may have the proceedings of the board reviewed by certiorari to the appropriate circuit court (Compiled Laws of Florida, 1927, section 3415). In this case, charges against a physician were filed with the board and a time and place for a hearing were fixed, but no copy of the charges nor notice of the time and place of hearing was served. At the time and place appointed the board peremptorily revoked the license without affording the licentiate a chance to defend. He thereafter sought a writ of mandamus to compel the board to reinstate his license. The board contended, however, that the writ of mandamus did not lie, because the medical practice act provided a complete and adequate remedy through a writ of certiorari. But, said the Supreme Court of Florida, the statute relied on by the board provides a complete and adequate remedy, other than mandamus, only for a licentiate whose license has been revoked after compliance with its terms. In the statute certain fundamental rights of an accused licentiate are set out. Their observance is mandatory, but in this case they were ignored by the board. The license was revoked in this case in a manner contrary to the spirit of our institutions and directly opposed to the letter of the law governing such revocation. There is, therefore, *nothing for the circuit court* to review on which it could predicate its judgment. The aggrieved physician in this case is entitled to have his license reinstated as prayed for in the writ, subject to proper proceedings under the statute.—*State ex rel. Tullidge v. Hollingsworth (Fla.), 138 So. 372.*

Evidence: Use of Mortality Tables.—When injuries which are the basis of actions for damages amount to permanent incapacity, mortality tables are commonly used to assist the jury in estimating the plaintiff's expectancy of life and in determining the probable duration of incapacity. Such tables give only the average of a large number of lives; in the individual case the expectancy may be higher or lower than the average. According to the Supreme Court of Errors of Connecticut, while mortality tables are generally held to be admissible, they are not conclusive. They are not the only evidence admissible in proof of expectancy of life; the jury may determine this from other evidence, such as evidence of the age, health, habits and physical condition.—*Donoghue v. Smith (Conn.), 157 Atl. 415.*

COMING MEETINGS

American Academy of Ophthalmology and Otolaryngology, Montreal, Sept. 19-23. Dr. William P. Wherry, 1500 Medical Arts Building, Omaha, Neb., Executive Secretary.

American Association of Obstetricians, Gynecologists and Abdominal Surgeons, French Lick, Indiana, Sept. 12-14. Dr. Magnus A. Tate, 19 West Seventh Street, Cincinnati, Secretary.

American Congress of Physical Therapy, New York, Sept. 6-10. Dr. F. B. Balmer, 185 North Wabash Avenue, Chicago, Secretary.

American Hospital Association, Detroit, Sept. 12-16. Dr. Bert W. Caldwell, 18 East Division Street, Chicago, Executive Secretary.

American Physical Therapy Association, Detroit, September 28-30. Dr. C. C. Vinton, 585 West End Avenue, New York, Secretary.

American Roentgen Ray Society, Detroit, September 27-30. Dr. Eugene P. Pendergrass, 3400 Spruce Street, Philadelphia, Secretary.

Colorado State Medical Society, Estes Park, Sept. 8-10. Mr. Harvey T. Sethman, 227 16th Street, Denver, Executive Secretary.

Delaware, Medical Society of, Lewes, September 27-28. Dr. W. O. La Motte, 604 Medical Arts Building, Wilmington, Secretary.

Idaho State Medical Association, Pocatello, Sept. 16-17. Dr. Harold W. Stone, 105 North Eighth Street, Boise, Secretary.

Indiana State Medical Association, Michigan City, September 27-29. Mr. T. A. Hendricks, 23 East Ohio Street, Indianapolis, Executive Secretary.

Kentucky State Medical Association, Louisville, October 3-6. Dr. A. T. McCormack, 532 West Main Street, Louisville, Secretary.

Michigan State Medical Society, Kalamazoo, Sept. 13-15. Dr. F. C. Warnshuis, 148 Monroe Avenue, Grand Rapids, Secretary.

Nevada State Medical Association, Reno, Sept. 23-24. Dr. Horace J. Brown, 120 North Virginia Street, Reno, Secretary.

Oregon State Medical Society, Klamath Falls, Sept. 22-24. Dr. Albert W. Holman, 410 Taylor Street, Portland, Secretary.

Pennsylvania, Medical Society of the State of, Pittsburgh, October 3-6. Dr. Walter F. Donaldson, 500 Penn Avenue, Pittsburgh, Secretary.

Utah State Medical Association, Ogden, Sept. 15-17. Dr. Leland R. Cowan, 305 Medical Arts Building, Salt Lake City, Secretary.

Vermont State Medical Society, Burlington, October 6-7. Dr. William G. Ricker, 31 Main Street, St. Johnsbury, Secretary.

Washington State Medical Association, Tacoma, Sept. 12-14. Dr. Curtis H. Thomson, 1305 Fourth Avenue, Seattle, Secretary.

Wisconsin, State Medical Society of, Milwaukee, Sept. 14-16. Mr. J. G. Crownhart, 119 East Washington Avenue, Madison, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Issues of periodicals are kept on file for a period of five years only. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending, but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

16: 439-680 (May) 1932

*Ovarian Neoplasms: Some Points in Their Pathology, Clinical Features and Treatment. W. B. Bell and M. M. Datnow.—p. 439.
*Malignant Tumors of Thymus Gland. E. H. Crosby, Albany, N. Y.—p. 461.
*Chronic Lactation Mastitis, Suppurative and Nonsuppurative: Difficulty of Distinguishing It from Cancer Clinically, at Exploratory Incision, from Its Fresh Appearance and in Microscopic Section: Analysis of Forty-Three Cases. L. C. Cohn, with Remarks by J. C. Bloodgood, Baltimore.—p. 487.
*Note on Occurrence of Herpes Zoster in Hodgkin's Disease, Lymphosarcoma, and the Leukemias. L. F. Craver and C. D. Haagensen, New York.—p. 502.
*Tumors of Maxillary Sinus. W. T. Peyton, Minneapolis.—p. 515.
Melanoma in Negro. E. L. Bishop, Atlanta, Ga.—p. 522.
Multiple Myeloma of Bone: Report of Two Cases with Remarks on Histogenesis. H. W. Williams, Providence, R. I.—p. 540.
Histologic Reaction of Muscle Tissue to Presence of Rapidly Growing Malignant Tumor. R. S. Leadingham, Atlanta, Ga.—p. 556.
Postmortem Observations of One Hundred and Fifty-Eight Cases of Carcinoma of Stomach. W. G. Harding 2d and F. D. Hankins, Los Angeles.—p. 561.
*Liver Diet and Tumor Growth. W. H. Woglom, New York.—p. 564.
*Comparative Study of Transplantability of Eight Mammary Gland Tumors Arising in Inbred Mice. A. M. Cloudman, Bar Harbor, Maine.—p. 568.
Influence of Time Factor in Irradiation of Drosophila Eggs. H. Roesler and P. S. Henshaw, New York.—p. 631.
Influence of Sex and Heredity on Development of Tar Tumors. M. C. Reinhard and C. F. Candee, Buffalo.—p. 640.
Melanoma of Caruncle: Case. V. A. Chapman, Milwaukee and Pasadena, Calif.—p. 645.
Indeterminate Lesion (Neoplasm?) in Albino Patient. E. Fischel and L. H. Jorstad, St. Louis.—p. 650.
Lymphosarcoma with Ovarian Involvement in Child. H. H. van Horn, Harrisburg, Pa.—p. 658.
Leiomyosarcoma of Cecum: Case. R. Trygstad, Brightwaters, N. Y.—p. 662.
Endothelioma of Lymph Nodes of Inguinal Region. N. P. Duany and E. Rivero, Havana, Cuba.—p. 665.

Ovarian Neoplasms.—Bell and Datnow show that in tumors of the ovary the previous history of the patient is of considerable importance, especially with respect to malignant neoplasms. The average age of patients with both innocent and malignant neoplasms, except cystic teratomas and possible sarcomas, falls between 42 and 50 years—the period of reproductive involution. A large majority of all women with ovarian neoplasms, innocent and malignant, are parous. The symptomatology is somewhat ambiguous in that menstrual disturbances may be due to associated uterine lesions rather than to the ovarian neoplasms. Abdominal pain and loss of weight, however, are important indications of malignancy. The physical sign of ascites cannot be relied on as a determining factor in the diagnosis since it is frequently present with innocent solid, and occasionally cystic, ovarian tumors. Ascites is observed only in certain well defined circumstances and is due to mechanical or chemical irritation of the peritoneum. Treatment is entirely surgical and should always be practiced in cases of innocent neoplasms. With these lesions, conservation of normal ovarian substance should be attempted in young women. Difficulties in diagnosis may sometimes deter the surgeon from acting in this manner. In parous women about or after the menopause, who form the majority of all cases, bilateral salpingo-oophorectomy with panhysterectomy should be done. If the patient is nulliparous, supravaginal hysterectomy with salpingo-oophorectomy is sufficient. In young parous women the removal of ovarian cysts by the vaginal route may be done with advantage. If laparotomy is performed, the tumor should be removed without preliminary tapping or puncture. The treatment of malignant neoplasms is curative or palliative. Lead therapy is often a useful adjunct to surgical procedures. Radiotherapy is not to be recommended.

Malignant Tumors of Thymus.—Crosby presents a typical case of thymic lymphocytoma in which the diagnosis was made at necropsy. The acute onset of symptoms and the rapidly fatal termination of the disease made diagnosis difficult and treatment futile. When such cases are seen early, roentgen therapy offers an excellent prognosis and even the hope of complete recovery. A discussion of the clinical course of malignant tumors of the thymus and a review of the physical signs, including the typical roentgen shadow, indicate that diagnosis can often be made early, and in early diagnosis and roentgen treatment lies the only hope for the patient. The author found 165 cases of malignant disease of the thymus in the literature, which, with the case he presents, make a total of 166 cases. Of these, 122 were sarcomas, so called, and 44 carcinomas.

Chronic Lactation Mastitis.—Cohn emphasizes the fact that mastitis is not always a clinical entity. It sometimes masquerades as cancer, while cancer may masquerade as mastitis. A palpable mass in the breast is said to be of the mastitis type if it feels like the caked breast of the nursing woman. If such a mass is associated with lactation and accompanied by fever and leukocytosis, exploration is indicated, on the diagnosis of acute lactation mastitis. In the absence of these cardinal signs, such masses have been observed in advanced carcinoma, comedo-adenoma with or without carcinoma, chronic lactation mastitis, chronic diffuse traumatic mastitis, tuberculous mastitis, and two types of chronic cystic mastitis—the shotty breast and diffuse dilatation of the ducts with mastitis. In studying sections of mastitis cases not associated with lactation, the author has been unable to find any case of acute or chronic mastitis, except in association with cancer, tuberculosis, diffuse dilatation of the ducts in chronic cystic mastitis, following trauma with a needle, or in association with hematoma after injury. It would seem, therefore, that mastitis is periductal or periacinal and is associated with dilatation of the ducts in chronic cystic mastitis, with lactation hypertrophy, or with trauma, tuberculosis or cancer. In chronic lactation mastitis the tumor begins as an area of induration. When explored early, it is found to be a solid, nonencapsulated area firmer than the surrounding breast tissue. If exploration is delayed, the induration disappears spontaneously, goes on to suppuration, or remains as a residual tumor. Chronic lactation mastitis is characterized microscopically by evidence of lactation hypertrophy (varying from the fully developed lobule of lactation to small areas of residual lactation hypertrophy) associated with infection. Microscopically, lactation hypertrophy has frequently been interpreted as carcinoma. It must be differentiated, also, from the pseudolactation hypertrophy sometimes seen in carcinoma. The infection may be simply an area of chronic inflammation in which small lymphocytes predominate, or there may be an abscess varying in size from one visible only under the microscope to the large abscess in which fluctuation can be elicited. Areas of residual lactation hypertrophy may be present in a breast many years after lactation. A tumor may follow a lactation mastitis immediately or may appear some time later. The longest interval in the author's series between lactation and the appearance of a tumor showing lactation hypertrophy was fourteen years.

Occurrence of Herpes Zoster in Hodgkin's Disease.—Craver and Haagensen report seven cases of secondary herpes zoster that were observed among 329 cases of lymphosarcoma, Hodgkin's disease and leukemia. On the basis of the clinical data it can be said only that these cases suggest that herpes zoster was due to the involvement of nervous structures by the tumor process. This relationship was most apparent in four cases in which herpes zoster developed at or near the same time that a focus of the neoplastic disease appeared on the same side of the body and in the same general anatomic region. The authors believe that the development of herpes zoster should suggest to the clinician the possibility of an underlying lymphosarcoma, Hodgkin's disease or leukemia.

Tumors of Maxillary Sinus.—Peyton calls attention to the fact that cancer of the antrum constitutes approximately 1 per cent of all cancer. Surgery alone, total excision of the maxilla, carries a high mortality (15 to 40 per cent) and results in few if any permanent cures. The author believes that with proper combination of surgery and radium five-year cures may be obtained in 10 per cent of all cancers of the antrum coming for treatment.

Liver Diet and Tumor Growth.—Woglom reports that, contrary to the results obtained by other investigators, the daily feeding of some 10 Gm. of fresh uncooked beef liver to each rat bearing sarcoma 8, 10, 39 or the Flexner-Jobling carcinoma had no demonstrable effect on the growth of any of these four tumor strains in 276 animals of a line employed at the Crocker Institute.

Transplantability of Mammary Tumors.—The carcinomas employed by Cloudman in his investigation occurred spontaneously in the mammary glands of females from the highly inbred A stock from Strong's laboratory, and their growth after transplantation was primarily dependent on susceptibility factors carried by the individuals of the A stock and transmitted by them into their hybrids. These tumors appear to need but few susceptibility factors for their continued growth after transplantation when compared with the experience of investigators who have used tumors of hybrid or of unknown genetic type. The histologic structure of these carcinomas does not indicate their degree of malignancy. The author verified the multiple factor hypothesis as the explanation of susceptibility to implanted tumors and demonstrated that the use of genetically controlled stocks is of major importance in detecting and analyzing the physiologic characteristics of transplanted tumors.

Physical Growth of Boys: Study by Means of Water Displacement. D. E. Zook, Chicago.—p. 1347.

Glycemia in Cachexia of Nurslings.—Jaso presents experimental data showing that in simple nutritional cachexias the blood sugar value is, on an average, 43 per cent lower than normal. The intensity of the hypoglycemia is in proportion to the denutrition. The presence of hypoglycemia was not confirmed in dystrophies of specific cause (syphilis, tuberculosis). The blood sugar remains within normal limits in hypothreptic infants in whose diet cereals are included. It returns to its normal value when the patient with athrepsia is progressing toward recovery. The blood sugar of nurslings can fall as low as 0.3 mg. per thousand cubic centimeters without clinical signs of hypoglycemia.

Human Milk Studies.—Under controlled methods of milk expression, sampling and analysis, Nims and her associates made extensive observations on three lactating women, two during two successive lactations of fourteen months' duration and a third during a single lactation period of similar duration. Observations were made also on another group of women during the earlier months of lactation. The nitrogen content of the milk decreased rapidly up to the sixth month and then remained fairly constant; the concentration of total ash and calcium decreased gradually; the phosphorus diminished gradually until the later months, when an increase occurred; the fat and total solids also decreased during the earlier months of lactation and then regained high values in late lactation. The data demonstrate that the various milk components, although varying from day to day and changing during lactation, fluctuate about a level that is characteristic for the individual woman, and that this individuality of fluctuation is maintained not only during one lactation but also through successive lactation periods. Over and above these individual trends in fluctuation, the composition of the milk in all three subjects showed a similar trend of changes as lactation progressed.

Levinson Test.—According to Gleich, the Levinson test is done thus: One cubic centimeter of spinal fluid is placed in each of the two test tubes 8 mm. in diameter. To one is added 1 cc. of a 1 per cent solution of mercuric chloride and, to the other, 1 cc. of a 3 per cent solution of sulphosalicylic acid. The tubes are well shaken, stoppered and allowed to stand at room temperature for forty-eight hours. At the end of twenty-four and forty-eight hours the column of precipitate in each tube is measured in millimeters. When the height of the precipitate in the first test tube is seen to be twice that of the precipitate in the second tube, the result of the test is positive. On the basis of his experience with the test in a large number of cases of tuberculous meningitis and other intracranial conditions, the author considers that the Levinson test is of value. Days before tubercle bacilli were found in the spinal fluid, if at all, or necropsies helped to confirm the diagnosis, the Levinson test was positive. In all the cases of tuberculous meningitis, the test was positive. In these cases the finding of tubercle bacilli or necropsy confirmed the reliability of the Levinson test. However, the test is corroborative and one should consider it together with the history, physical observations and clinical data in making a diagnosis.

Congenital Lesions of Heart.—The clinical records of sixty-two patients with congenital heart lesions, revealed at necropsy, of such a nature as to permit venous shunting, were studied by Leech in an attempt to determine the presence or absence of characteristic symptoms and signs. Nearly half of these patients did not present any clinical abnormalities referable to the circulatory apparatus. While the incidence of cyanosis, periodic as well as constant, was found to be somewhat higher in this group than among twenty other patients whose necropsies revealed congenital defects of the heart that did not permit venous shunting, this sign was found not to differentiate sufficiently the two general types of lesions. Eight (13 per cent, approximately) of the large group presented a syndrome that was almost totally absent in the smaller group with the nonvenous shunt type of defect. In the larger group, five additional patients presented convulsive seizures not accompanied by cyanosis and respiratory distress. In conclusion, the author states that when other causes, such as pneumonia, epilepsy, meningitis and severely toxic conditions, can be ruled out and when the patient is known to have congenital heart disease, the occurrence of convulsion-like seizures, often epileptiform in character, sometimes followed by drowsiness and frequently accompanied by hyperpnea, may justly be interpreted as an indication of a lesion, or a combination of lesions, that permits venous shunting, especially if the patient shows a constant cyanosis, no matter how slight, or if the attack is accompanied by a deep cyanosis.

Chronic Arthritis in Children.—Kuhns and Swaim call attention to the fact that disturbances in growth are not uncommon in chronic arthritis in children. Such disturbances may appear only after several years of the disease and are found oftenest in children with poor health and resistance. These disturbances, while they are influenced by nonuse of the body and by nutritional and endocrine dysfunction, are due chiefly to the involvement of the proliferating epiphyseal cartilages, resulting in early ossification. They are dependent on the severity and chance location of the arthritis. There are three general types of disturbances in growth in chronic arthritis. The commonest of these is the persistence of infantile proportions in the hands and feet. Shortness of an extremity or a portion of an extremity, or symmetrical shortening of two limbs, is fairly common. Dwarfism is relatively rare but occurs in cases of severe generalized arthritic involvement. The prevention and cure of these disturbances rest, first, on general measures to combat the disease in its early stage and to improve the general condition of the patient as rapidly as possible, and, secondly, on local measures to improve the function of the extremities and to promote circulation. The authors believe that every child with chronic arthritis should be observed at regular intervals for at least five years after the disease is quiescent.

Emotional Problems Related to Breast Feeding.—Childers and Hamil reviewed the social histories of 469 children under 13 years of age referred to the Neuro-Psychiatric Clinic of Harper Hospital, Detroit, and tabulated objectionable behavior manifestations. The various symptoms of behavior, calculated in percentage of frequency of occurrence, were plotted in a curve for the entire number, and these items in the same order were in similar manner plotted for four groups into which the 469 cases were divided. The graphs seem to show that undesirable behavior manifestations are generally greater among those children who were weaned between the first and sixth months of infancy. Those children who were never breast fed have the next greatest percentage frequency of such manifestations. The group in which breast feeding was continued into the "normal" period for weaning reveals a smaller percentage of undesirable conduct manifestations than the two foregoing groups. The group in which breast feeding was prolonged beyond the eleventh month shows the smallest percentages of undesirable behavior traits but the difference between this and the immediate foregoing group is not marked. The children who were weaned between the first and fifth months show the highest percentage of abnormal behavior manifestations. The explanation assumed for this group being so involved is that these children, becoming adapted to breast feeding and then being called on to adjust to bottle feeding, had certain emotional conditionings to which the other groups were not subjected in so great a degree.

Subcutaneous Nodules in Chronic Arthritis.—Clawson and Wetherby studied 200 patients having chronic arthritis, to determine the frequency of subcutaneous nodules in this disease. Nodules varying in diameter from 5 mm. to 3 cm., and in number from one to several per patient, were found in 29.5 per cent of the cases. Structurally these nodules seemed to be similar to those found in acute rheumatic fever and to those produced in animals by injecting streptococci. They tended to be larger in chronic arthritis. The microscopic structure was chiefly polyblastic in character, but small areas of necrosis and abscess formation were commonly seen. When these nodules were macerated under sterile conditions and cultures taken in beef infusion dextrose broth, diplococci morphologically and culturally similar to those commonly found in the blood of patients having acute rheumatic fever or chronic arthritis were isolated in 70.6 per cent of the cases. The frequency of the subcutaneous nodules in acute rheumatic fever and chronic arthritis, the similarity of the gross and microscopic structure of the nodules in these two conditions and in experimental streptococcic nodules, and the frequency with which streptococci are yielded by cultures from the blood in acute rheumatic fever and from the blood and nodules in chronic arthritis, strongly suggest that acute rheumatic fever and chronic arthritis for the most part have a common streptococcic etiology and that the two diseases are in all probability different manifestations of the same process.

Radon and Histocyte in Liver of Rat.—Higgins and Rogers report the results of a study of the reaction of the histocytes in the liver to radon, as contained in gold radon seeds. Similar but inactive gold seeds were used in a series of control animals to determine the local reaction to such foreign bodies. All local histocytes within the vicinity of the inactive gold seed responded immediately to the foreign body by retracting their processes, desquamating into the sinusoids or migrating into adjacent parenchyma. Their function as littoral histocytes had apparently ceased and they were not concerned in an attack on the foreign body. Seventy-two hours after insertion of the inactive seed into the parenchyma, an effective barrier had been formed around it by these actively migrating histocytes. Subsequently these cells contributed toward the formation of connective tissue. All histocytes in the vicinity of the active radon seed were as susceptible to the emanation as the cells of the parenchyma. The extent of the destruction by the radon increased until the maximal injury was reached about the thirty-fifth day. Histocytes within the zone of injury were destroyed, and those immediately beyond did not manifest signs of restorative activity during this period. After the fifth week, however, a retarded restorative activity was manifested by the histocytes just peripheral to the zone of maximal injury. By the tenth or twelfth week these cells considerably remote from the radon seed, and which either had not been affected or only slightly affected by the radon, migrated rapidly toward the seed and contributed toward the formation of a wall comparable to that seen three days after the implantation of the control seed.

Studies of Blood of Natives at High Altitude.—Hurtado presents a number of observations on certain of the blood characteristics of the Indian natives of the Peruvian Andes. The investigation was conducted at an altitude of 14,890 feet (4,532 meters) and with an average barometric pressure of 410 mm. of mercury. The subjects studied were carefully selected as normal men, and the results obtained suggest the following conclusions. 1. Observations on the erythrocyte count gave an average increase of about a million red cells per cubic millimeter over the normal value at sea level, but a considerable percentage of these natives live with a red cell count which would be considered normal at sea level. This observation indicates that an increase in the erythrocytes of the circulating blood, although the common condition, is not an essential adaptation process for normal life at high altitudes. There is no relationship between the red cell count and age or body measurements. 2. The average number of grams of hemoglobin per hundred cubic centimeters of blood has almost the same value as the normal average at sea level. In only 50 per cent of the cases was a higher result obtained. Each red cell at high altitude contains less hemoglobin, as compared with the normal erythrocyte at sea level, but the corpuscular hemoglobin is not a fixed characteristic: it varies inversely with the level of the red cell count; that is, the higher the count the less hemoglobin in each cell, and vice versa. Oxygen determinations in arterial and venous blood verify these observations and indicate that the red cell comes to the tissues with a lower oxygen content as compared with the erythrocyte at sea level. 3. There is a marked increase in the hematocrit (percentage of erythrocytes), and it is proportionally greater than the increase in the red cell count, with the result that each erythrocyte has a larger volume (as compared with the normal corpuscle at sea level). Again the corpuscular volume is not a fixed characteristic: it varies inversely with the level of the red cell count. The larger size of the erythrocyte was also confirmed by direct measurement of its diameter. 4. The diminished amount of hemoglobin in a larger corpuscle gives a lower value for the concentration of that substance in relation to the volume of the cell. Only about one fourth of the erythrocyte is saturated with hemoglobin. Equal and parallel changes in cell volume and hemoglobin, under the influence of variations in the red cell count, keep remarkably constant such concentration. There is an almost perfect inverse correlation between the hematocrit and the hemoglobin concentration in each red cell. These observations suggest that the adaptation processes to the high altitude, from the point of view of blood morphology, are to be found not primarily in red cell count and hemoglobin increases, as it has often been remarked, but rather in a fine and close correlation between cell number, volume and hemoglobin, and in the existence of a larger surface area in a given volume of blood and in the individual erythrocyte for the hemoglobin and oxygen content, factors which would favor the proper supply of this gas to the tissues, this last process being perhaps the basic and fundamental problem at high altitude.

Excretion of Estrin by Women.—The Smiths gave estrin orally to women, whose urines were followed for its excretion over a period of one or two months. Eight cases are reported, including four amenorrheic patients, three sterile women, and one normal control. The results would indicate that in women, as in rabbits, estrin is excreted only when the organism has been exposed to the action of corpus luteum. It appears possible by this means to differentiate between a persistent corpus luteum, irregular appearance or total absence of corpus luteum, and cyclic activity of the corpus luteum.

Drainage of Mucus in Accessory Sinuses.—Hilding describes an experiment in which he demonstrated that the drainage of the frontal sinus of a dog was effected by means of the movement of a lining film or web of mucin motivated by ciliary action. The film was extremely thin but of high viscosity and had sufficient tensile strength to sustain a considerable degree of traction. This traction was a very important factor in the drainage. The direction of motion was that of a flat, lateral spiral so arranged that there was but little tension from conflicting currents in the film of mucin. There was a speed gradient of fairly uniform acceleration (when numerous tests were averaged); the speed at the ostium was four to six times as great as that on the mesial wall. Several different materials were used to test the time required to raise small volumes from the deepest recess of the sinus, upward to the level of the ostium. All were moved more or less successfully, but thick, mucilaginous mucin was moved most completely and rapidly. Roughly, one or two hours was required to move out 1 cc. of thick mucin. A longer time was required to remove creamy pus, and still longer to remove watery substances. Clinical application of these facts can be made readily, if conditions in the sinuses of man are similar, as presumably they are. If bacteria gain access to a sinus and lodge in the film of mucin on the walls, they are swept out in a very short time. If a volume of fluid gains access, or a volume of secretion forms, a much longer time is required to remove it. In general, the more mucin there is in the secretion, the better it drains. Pus drains poorly on account of its physical properties. In addition it may contain toxins or other materials that destroy ciliary action.

Pneumoventriculography and Encephalography.—Adson considers ventriculography a valuable aid to differential diagnosis and localization of brain tumors. However, it should not be used indiscriminately; neither should it be substituted for thorough neurologic examination. Occasionally it may be employed to supply confirmatory evidence, or when the localizing clinical evidence is vague. It serves, also, as a therapeutic agent in avoiding unnecessary exploratory craniotomy by revealing normal ventricles or a subcortical, inaccessible tumor of the midbrain. The complications and the fatalities may be minimized by intravenous administration of hypertonic solutions, saline cathartics, and enemas, by repeated ventricular punctures, and by early exploration. Encephalography is of greatest value in the differential diagnosis and localization of arachnoiditis, posttraumatic lesions, and atrophy of the brain. Occasionally, it may be used as an aid to localization in cases in which tumor of the brain is suspected, without evidence of increased intracranial pressure. It is the author's impression that the use of encephalography is being abused, since the clinical features, often, are sufficient to make possible the diagnosis without subjecting the patient to the distressing symptoms of the procedure.

Encephalography in Children.—Eley and Vogt state that encephalography is a valuable diagnostic procedure in the study of children with fixed lesions of the brain. The information obtained warrants the dangers involved. The judicious employment of this procedure should eventually lead to a better understanding and classification of such conditions as epilepsy, feeblemindedness, and cerebral palsy occurring in children. From the encephalograms alone, however, one is unable to determine the nature of the initial etiologic agent responsible for the ultimate gross pathologic changes.

Roentgenograms of Pituitary Tumors.—According to Pancoast, roentgenologists must admit that the roentgenographic diagnosis of pituitary tumors is by no means *infallible*, even aside from the difficulties in interpretation between their effects and the deformations of the sella produced by suprasellar and metasellar growths and rarely parasellar lesions. The ophthalmologist and the neurologist will also admit that the clinical manifestations of hypophyseal adenomas are not always typical. Satisfactory explanations for the discrepancies in characteristic roentgenographic appearances and clinical phenomena of the pituitary tumors are to be found in (1) peculiarities or variations in the sella turcica, (2) variations in the location of the optic chiasm, (3) anomalies and abnormalities in the constituent parts of the circle of Willis, and (4) variations in the location of the infundibulum. All these explanations are given, as far as possible, on the basis of careful anatomic and necropsy studies, operative observations and correlation of roentgenographic appearances with clinical, operative and postmortem observations. The author describes the normal anatomic and roentgenographic appearances of the sella turcica and variations therefrom within normal limits. As the sella is the key to the diagnostic situation in so many cases of intracranial lesions in various localities, a classification on the basis of sellar changes is strongly advocated, as follows: (1) intrasellar tumors (adenomas); (2) suprasellar growths, originating either from vestigial remnants of the craniopharyngeal pouch or from other midline structures nearby; (3) parasellar lesions arising in the middle fossa near the sella and deforming the latter directly or through the agency of the internal carotid artery, and (4) metasellar tumors, deforming through the agency of a dilated third ventricle enlarged from ventricular block below it. The differential points of distinction of each group are discussed, together with the effects of certain other causes of sellar deformation.

Chronic Progressive Bulbar Palsy.—Christie believes that chronic bulbar palsy should always be thought of in cases of difficulty in swallowing when the delay is in the pharynx. Roentgen examination serves to differentiate between obstruction to the lumen and deficient muscular action of the constrictors. Neurologic examination will usually serve to differentiate further between central lesions, those of the pons and medulla, and peripheral neuritis.

Contrast Medium Roentgenography in Thoracic Surgery.—Hedblom and van Hazel call attention to the fact that there are certain types of thoracic disease in which contrast medium roentgenography is especially valuable. First among these is bronchiectasis, and second that group of long standing suppurative processes in which the whole affected portion of the lung, because of fibrosis, pleural thickening, or fluid, presents a more or less diffuse clouding and in which the physical signs are similarly masked. In some cases of these conditions the opacity is so dense that even iodized oil fails to produce a very clear contrast shadow. In most instances, however, it shows the nature of the lesion when all other methods fail. In some types of empyema and of chronic tuberculosis it is of distinct help in diagnosis.

Sunstroke and Allied Conditions in the United States.—Shattuck and Hilferty present the results of a statistical study which shows that the higher death rates attributed to excessive heat including sunstroke are distributed with great irregularity in the United States. As a rule, the death rates were markedly higher in urban than in rural localities. This feature becomes highly pronounced in years when the deaths from heat have been notably frequent. The rates fluctuate markedly from year to year, but a slight downward trend is indicated. The average death rates by ages are relatively high during the first year of life, and very low thereafter up to the age of 20. They then begin to rise gradually. After the age of 70, the rates rise sharply. The death rate from heat effects in states having a large Negro population is 2.4 times as high for the colored as for the white. This is approximately true for both sexes. A correlation with occupation is suggested by these figures. The reporting of deaths from excessive heat in every month of the year points to industrial conditions as causative of many of these cases. Although means of evaluating the importance of suitable clothing are not available, there are indications that it is a factor which should not be overlooked.

Epidermophytids.—In summarizing an analysis of the clinical concept of the palmar and digital epidermophytids, Scholtz emphasizes the following points: 1. Bacteriologic evidence presented by him cannot be accepted as conclusive, because the claim of uniformly negative observations in the lesions of the hand is not concurred in by other observers. 2. The trichophyton test is not specific, and because of its persistent nature it is conducive to false positive tests and vague and uncertain clinical deductions. 3. Positive blood cultures and the experimental reproduction of mycotic dyshidrotic lesions are of argumentative importance, but so far they have been found positive in so few isolated cases as hardly to be definite proof of the conception of epidermophytids. 4. From a clinical point of view the conception of palmar and digital epidermophytids gives rise to many unsolved questions and unexplainable clinical problems; it rests also on statements and observations so conflicting with general dermatologic experience as to render it inacceptable without further clinical elucidation.

Lupus Erythematosus.—Madden calls attention to the fact that acute disseminated lupus erythematosus is an important clinical entity. The symptoms are more or less constant, but the degree of severity varies greatly. Constitutional symptoms may completely overshadow the cutaneous symptoms. Albuminuria was a constant finding in six fatal cases reported by the author. Its presence may be of definite prognostic value. In fatal cases leukocytosis does not develop, even when conditions arise in which it would be expected. The histopathology is not an important diagnostic aid but is suggestive and worthy of study. The disease has the characteristics of a septicemia or toxemia. Streptococci have been repeatedly reported to be present in the blood stream. Tuberculosis has not been proved to be an etiologic factor in many instances, but the newer work must be evaluated before tubercle bacilli are excluded as a probable cause. There is no specific therapy. The prognosis is grave, even when there is apparent recovery, for relapses are the rule.

Studies of Blood of Natives at High Altitude.—Hurtado presents a number of observations on certain of the blood characteristics of the Indian natives of the Peruvian Andes. The investigation was conducted at an altitude of 14,890 feet (4,532 meters) and with an average barometric pressure of 410 mm. of mercury. The subjects studied were carefully selected as normal men, and the results obtained suggest the following conclusions. 1. Observations on the erythrocyte count gave an average increase of about a million red cells per cubic millimeter over the normal value at sea level, but a considerable percentage of these natives live with a red cell count which would be considered normal at sea level. This observation indicates that an increase in the erythrocytes of the circulating blood, although the common condition, is not an essential adaptation process for normal life at high altitudes. There is no relationship between the red cell count and age or body measurements. 2. The average number of grams of hemoglobin per hundred cubic centimeters of blood has almost the same value as the normal average at sea level. In only 50 per cent of the cases was a higher result obtained. Each red cell at high altitude contains less hemoglobin, as compared with the normal erythrocyte at sea level, but the corpuscular hemoglobin is not a fixed characteristic: it varies inversely with the level of the red cell count; that is, the higher the count the less hemoglobin in each cell, and vice versa. Oxygen determinations in arterial and venous blood verify these observations and indicate that the red cell comes to the tissues with a lower oxygen content as compared with the erythrocyte at sea level. 3. There is a marked increase in the hematocrit (percentage of erythrocytes), and it is proportionally greater than the increase in the red cell count, with the result that each erythrocyte has a larger volume (as compared with the normal corpuscle at sea level). Again the corpuscular volume is not a fixed characteristic: it varies inversely with the level of the red cell count. The larger size of the erythrocyte was also confirmed by direct measurement of its diameter. 4. The diminished amount of hemoglobin in a larger corpuscle gives a lower value for the concentration of that substance in relation to the volume of the cell. Only about one fourth of the erythrocyte is saturated with hemoglobin. Equal and parallel changes in cell volume and hemoglobin, under the influence of variations in the red cell count, keep remarkably constant such concentration. There is an almost perfect inverse correlation between the hematocrit and the hemoglobin concentration in each red cell. These observations suggest that the adaptation processes to the high altitude, from the point of view of blood morphology, are to be found not primarily in red cell count and hemoglobin increases, as it has often been remarked, but rather in a fine and close correlation between cell number, volume and hemoglobin, and in the existence of a larger surface area in a given volume of blood and in the individual erythrocyte for the hemoglobin and oxygen content, factors which would favor the proper supply of this gas to the tissues, this last process being perhaps the basic and fundamental problem at high altitude.

Excretion of Estrin by Women.—The Smiths gave estrin orally to women, whose urines were followed for its excretion over a period of one or two months. Eight cases are reported, including four amenorrheic patients, three sterile women, and one normal control. The results would indicate that in women, as in rabbits, estrin is excreted only when the organism has been exposed to the action of corpus luteum. It appears possible by this means to differentiate between a persistent corpus luteum, irregular appearance or total absence of corpus luteum, and cyclic activity of the corpus luteum.

Drainage of Mucus in Accessory Sinuses.—Hilding describes an experiment in which he demonstrated that the drainage of the frontal sinus of a dog was effected by means of the movement of a lining film or web of mucin motivated by ciliary action. The film was extremely thin but of high viscosity and had sufficient tensile strength to sustain a considerable degree of traction. This traction was a very important factor in the drainage. The direction of motion was that of a flat, lateral spiral so arranged that there was but little tension from conflicting currents in the film of mucin. There was a speed gradient of fairly uniform acceleration (when numerous tests were averaged); the speed at the ostium was four to six times as great as that on the mesial wall. Several different materials were used to test the time required to raise small volumes from the deepest recess of the sinus, upward to the level of the ostium. All were moved more or less successfully, but thick, mucilaginous mucin was moved most completely and rapidly. Roughly, one or two hours was required to move out 1 cc. of thick mucin. A longer time was required to remove creamy pus, and still longer to remove watery substances. Clinical application of these facts can be made readily, if conditions in the sinuses of man are similar, as presumably they are. If bacteria gain access to a sinus and lodge in the film of mucin on the walls, they are swept out in a very short time. If a volume of fluid gains access, or a volume of secretion forms, a much longer time is required to remove it. In general, the more mucin there is in the secretion, the better it drains. Pus drains poorly on account of its physical properties. In addition it may contain toxins or other materials that destroy ciliary action.

Pneumoventriculography and Encephalography.—Adson considers ventriculography a valuable aid to differential diagnosis and localization of brain tumors. However, it should not be used indiscriminately; neither should it be substituted for thorough neurologic examination. Occasionally it may be employed to supply confirmatory evidence, or when the localizing clinical evidence is vague. It serves, also, as a therapeutic agent in avoiding unnecessary exploratory craniotomy by revealing normal ventricles or a subcortical, inaccessible tumor of the midbrain. The complications and the fatalities may be minimized by intravenous administration of hypertonic solutions, saline cathartics, and enemas, by repeated ventricular punctures, and by early exploration. Encephalography is of greatest value in the differential diagnosis and localization of arachnoiditis, posttraumatic lesions, and atrophy of the brain. Occasionally, it may be used as an aid to localization in cases in which tumor of the brain is suspected, without evidence of increased intracranial pressure. It is the author's impression that the use of encephalography is being abused, since the clinical features, often, are sufficient to make possible the diagnosis without subjecting the patient to the distressing symptoms of the procedure.

Encephalography in Children.—Eley and Vogt state that encephalography is a valuable diagnostic procedure in the study of children with fixed lesions of the brain. The information obtained warrants the dangers involved. The judicious employment of this procedure should eventually lead to a better understanding and classification of such conditions as epilepsy, feeblemindedness, and cerebral palsy occurring in children. From the encephalograms alone, however, one is unable to determine the nature of the initial etiologic agent responsible for the ultimate gross pathologic changes.

Roentgenograms of Pituitary Tumors.—According to Pancoast, roentgenologists must admit that the roentgenographic diagnosis of pituitary tumors is by no means infallible, even aside from the difficulties in interpretation between their effects and the deformations of the sella produced by suprasellar and metasellar growths and rarely parasellar lesions. The ophthalmologist and the neurologist will also admit that the clinical manifestations of hypophyseal adenomas are not always typical. Satisfactory explanations for the discrepancies in characteristic roentgenographic appearances and clinical phenomena of the pituitary tumors are to be found in (1) peculiarities or variations in the sella turcica, (2) variations in the location of the optic chiasm, (3) anomalies and abnormalities in the constituent parts of the circle of Willis, and (4) variations in the location of the infundibulum. All these explanations are given, as far as possible, on the basis of careful anatomic and necropsy studies, operative observations and correlation of roentgenographic appearances with clinical, operative and postmortem observations. The author describes the normal anatomic and roentgenographic appearances of the sella turcica and variations therefrom within normal limits. As the sella is the key to the diagnostic situation in so many cases of intracranial lesions in various localities, a classification on the basis of sellar changes is strongly advocated, as follows: (1) intrasellar tumors (adenomas); (2) suprasellar growths, originating either from vestigial remnants of the craniopharyngeal pouch or from other midline structures nearby; (3) parasellar lesions arising in the middle fossa near the sella and deforming the latter directly or through the agency of the internal carotid artery, and (4) metasellar tumors, deforming through the agency of a dilated third ventricle enlarged from ventricular block below it. The differential points of distinction of each group are discussed, together with the effects of certain other causes of sellar deformation.

Chronic Progressive Bulbar Palsy.—Christie believes that chronic bulbar palsy should always be thought of in cases of difficulty in swallowing when the delay is in the pharynx. Roentgen examination serves to differentiate between obstruction to the lumen and deficient muscular action of the constrictors. Neurologic examination will usually serve to differentiate further between central lesions, those of the pons and medulla, and peripheral neuritis.

Contrast Medium Roentgenography in Thoracic Surgery.—Hedblom and van Hazel call attention to the fact that there are certain types of thoracic disease in which contrast medium roentgenography is especially valuable. First among these is bronchiectasis, and second that group of long standing suppurative processes in which the whole affected portion of the lung, because of fibrosis, pleural thickening, or fluid, presents a more or less diffuse clouding and in which the physical signs are similarly masked. In some cases of these conditions the opacity is so dense that even iodized oil fails to produce a very clear contrast shadow. In most instances, however, it shows the nature of the lesion when all other methods fail. In some types of empyema and of chronic tuberculosis it is of distinct help in diagnosis.

Sunstroke and Allied Conditions in the United States.—Shattuck and Hilferty present the results of a statistical study which shows that the higher death rates attributed to excessive heat including sunstroke are distributed with great irregularity in the United States. As a rule, the death rates were markedly higher in urban than in rural localities. This feature becomes highly pronounced in years when the deaths from heat have been notably frequent. The rates fluctuate markedly from year to year, but a slight downward trend is indicated. The average death rates by ages are relatively high during the first year of life, and very low thereafter up to the age of 20. They then begin to rise gradually. After the age of 70, the rates rise sharply. The death rate from heat effects in states having a large Negro population is 2.4 times as high for the colored as for the white. This is approximately true for both sexes. A correlation with occupation is suggested by these figures. The reporting of deaths from excessive heat in every month of the year points to industrial conditions as causative of many of these cases. Although means of evaluating the importance of suitable clothing are not available, there are indications that it is a factor which should not be overlooked.

Epidermophytids.—In summarizing an analysis of the clinical concept of the palmar and digital epidermophytids, Scholtz emphasizes the following points: 1. Bacteriologic evidence presented by him cannot be accepted as conclusive, because the claim of uniformly negative observations in the lesions of the hand is not concurred in by other observers. 2. The trichophyton test is not specific, and because of its persistent nature it is conducive to false positive tests and vague and uncertain clinical deductions. 3. Positive blood cultures and the experimental reproduction of mycotic dyshidrotic lesions are of argumentative importance, but so far they have been found positive in so few isolated cases as hardly to be definite proof of the conception of epidermophytids. 4. From a clinical point of view the conception of palmar and digital epidermophytids gives rise to many unsolved questions and unexplainable clinical problems; it rests also on statements and observations so conflicting with general dermatologic experience as to render it inacceptable without further clinical elucidation.

Lupus Erythematosus.—Madden calls attention to the fact that acute disseminated lupus erythematosus is an important clinical entity. The symptoms are more or less constant, but the degree of severity varies greatly. Constitutional symptoms may completely overshadow the cutaneous symptoms. Albuminuria was a constant finding in six fatal cases reported by the author. Its presence may be of definite prognostic value. In fatal cases leukocytosis does not develop, even when conditions arise in which it would be expected. The histopathology is not an important diagnostic aid but is suggestive and worthy of study. The disease has the characteristics of a septicemia or toxemia. Streptococci have been repeatedly reported to be present in the blood stream. Tuberculosis has not been proved to be an etiologic factor in many instances, but the newer work must be evaluated before tubercle bacilli are excluded as a probable cause. There is no specific therapy. The prognosis is grave, even when there is apparent recovery, for relapses are the rule.

Spirochetosis and Experimental Syphilis.—According to Fried and Orlov, spontaneous spirochetosis is an autonomous disease found in rabbits (and probably in the field hare). The infection is caused by Spirochaeta cuniculi and is transmitted from animal to animal by genital contact only, leading to a chronic disease of the skin in the anogenital region (and, in females, of the mucosa) and sometimes also of other parts of the body. The process is sometimes accompanied by a regional adenopathy. The occasional presence of spirochetes in the tributary lymph nodes and also in the blood previously reported by others was not confirmed in the authors' studies. The Wassermann and Sachs-Georgi reactions are, as a rule, negative in spontaneous spirochetosis. Animals cured of spontaneous spirochetosis are susceptible to new infections. Spirochaeta cuniculi causes no specific lesions in the viscera or in the central nervous system. Likewise the cerebrospinal fluid in this disease shows no cytologic or chemical changes. Spontaneous spirochetosis is a local parasitic disease of the skin which may be generalized in rare instances. It is believed that in spite of the morphologic identity of Spirochaeta cuniculi and Spirochaeta pallida, their biologic properties and the processes that they cause are entirely different. The two diseases can be differentiated by clinical and laboratory tests. In difficult cases the therapeutic test with bismuth or arsphenamine may be a reliable guide in the differential diagnosis. This study has revealed (as others also have observed) that, not infrequently, apparently normal rabbits show changes of the viscera, central nervous system and cerebrospinal fluid which resemble those seen in advanced syphilis in man. The results obtained from the study of the syphilitic disease of these organs in the rabbit must therefore be accepted with reservations.

Annular Macular Syphilid.—Combes describes annular macular lesions occurring in syphilis which, while clinically resembling those developing in early syphilis and in the relapsing roseola, are in reality not a cutaneous syphilid at all, in the histologic sense of the term, but rather a vascular manifestation of the disease. Their complete identity cannot be verified without a microscopic examination of the excised tissue, and then only when this is interpreted in correlation with the clinical features of the process. The apparent rarity of the condition may be readily explained. In the first place the eruption may be so faint as to escape notice, particularly in the absence of any subjective symptoms. Secondly, as it comes so long after the initial infection and because of its unusual and picturesque appearance, syphilis may not be suspected. It is most likely to be confused with erythema multiforme, pityriasis rosea, pityriasis versicolor, trichophytosis, seborrhea corporis and leprosy. From the cutaneous syphilids it may be differentiated by the fact that it is purely a circulatory disturbance and the clinical appearance is due solely to changes in the vascular network of the skin. Other classic characteristics are the complete absence of infiltration, the stability, chronicity and slow response to therapy.

Lissauer's Dementia Paralytica.—Merritt and Springlova review the clinical and pathologic reports in thirty-five cases of Lissauer's dementia paralytica in the literature and report eight additional cases. Their eight cases were characterized clinically by a relatively long duration, the presence of apoplectiform and epileptiform attacks, often jacksonian, and the appearance of localizing signs, such as hemiplegia and aphasia. Pathologically, they all showed macroscopic atrophy, usually unilateral, of certain convolutions, generally in the temporal lobe and inferior parietal lobe. Microscopically, they were characterized by the presence of status spongiosus in the cortex and myelin loss in the white matter of the atrophic convolutions. It is shown that these lesions are not produced by the usual dementia paralytica process alone, and on the basis of clinical and pathologic data it is concluded that they are produced by a combination of functional disturbance of the circulation with the dementia paralytica process. It is pointed out that the usual distribution of the atrophy in these cases agrees with the distribution of the posterior branches of the middle cerebral artery. It is also emphasized that there is nothing to separate sharply this type of case from the "usual" case of dementia paralytica. The differences would appear to be quantitative rather than qualitative. Functional disturbance of the circulation probably occurs in a much larger percentage of the cases of dementia paralytica than is represented by those diagnosed as Lissauer's dementia paralytica. Status spongiosus was found by Fischer in 10 per cent of cases of dementia paralytica, and it is probable that primary loss of myelin in the white matter would be found just as often if more thorough examinations were made.

Spontaneous Subarachnoid Hemorrhage.—Strauss and his associates describe thirty-four cases illustrating the syndrome of spontaneous subarachnoid hemorrhage. They call attention to the fact that the term "spontaneous subarachnoid hemorrhage" is limited to massive extravasation of blood into the subarachnoid space, caused by spontaneous rupture of a blood vessel; it excludes hemorrhages into the same space resulting from extension of intracerebral bleeding and minor bleeding in the course of systemic infections, blood disease or those occurring during agonal episodes. The syndrome is characterized by a relatively short prodromal period in which headache, dizziness, nausea and rigidity of the neck and spine are the most prominent manifestations. It is followed by an abrupt and explosive onset of the active stage, ushered in by violent headache, partial or total loss of consciousness, and occasionally convulsions. Examination discloses signs of meningeal irritation (rigidity of the neck and Kernig and Brudzinski signs), signs of increased intracranial tension (papilledema and depressed reflexes) and often palsies of extrinsic ocular muscles. At this stage the cerebrospinal fluid is usually bloody, occasionally xanthochromic and rarely clear. The clinical course may be short, the patient recovering in the course of several days, or stormy and protracted, lasting over a period of weeks (average in the authors' material, forty-six days). During the clinical course, neurologic and systemic manifestations may develop and disappear. Among the former are intellectual and emotional disturbances, approaching or developing into a confusional psychosis, progressive elevation of the disks, accentuation in the meningeal signs and cranial nerve palsies. Among the systemic manifestations are elevation of temperature, presenting an irregular curve, and leukocytosis. Recurrences of bleeding, with coincident recurrence of signs and symptoms, are not uncommon. They may occur during the initial attack in the character relapses. They may take the form of repeated attacks after a period of convalescence or after an apparent full recovery from a previous episode. Several recurrences may occur before a fatal attack. The recognition of the syndrome of spontaneous subarachnoid bleeding as differing from other forms of intracranial hemorrhage is essential, for the therapeutic indications differ. Treatment for spontaneous subarachnoid hemorrhage consists of repeated lumbar punctures to relieve symptoms of increased intracranial tension. Headache, the mental state, slowing of the pulse and papilledema are the guiding factors determining the need and frequency of this therapeutic measure. The prognosis is always grave, though not hopeless; satisfactory recoveries are frequent. The common anatomic changes are arteriosclerosis of the cerebral blood vessels, with or without frank aneurysmal defects. Inflammatory lesions of blood vessels are also capable of causing aneurysmal formation with ultimate rupture and hemorrhage. Spontaneous subarachnoid hemorrhage may occur at any age (from 10 to 70), though it is most frequent between the ages of 25 and 40. Spontaneous subarachnoid hemorrhage is a disease entity that should be clearly understood not only by the neurologist but also by the internist, who is more likely to be called on to diagnose and treat the condition in its acute stage.

Spontaneous Cerebral Hemorrhage.—According to Bagley, spontaneous cerebral bleeding, whether from meningeal or intracerebral vessels, is often the result of rupture of an aneurysm, which may vary in size from a fraction of a millimeter to several millimeters in diameter. Arteriosclerosis is the most common cause of these aneurysms, but syphilis, trauma, bacteriologic reactions and congenital defects of the arterial walls are responsible for the lesion in some cases, or the bleeding may be due to a direct rupture of an arteriosclerotic or a congenitally weak vessel wall without aneurysmal formation. Careful neurologic examination and grouping is essential so that the proper type of therapeutic procedure may be chosen. In the treatment of these patients, three conditions must be considered: (1) a sterile meningitis produced by the irritating effect of blood in the cerebrospinal fluid; (2) increased intracranial pressure produced by intracerebral or extracerebral clot; (3) disturbance of the cardiorespiratory and thermoregulatory centers seen in extensive extravasations or large clots at the base with destruction of the basal ganglions and rupture into the ventricle. The patient with the third symptomatology cannot be benefited surgically. Theoretically, blood in the cerebrospinal fluid, as well as intracerebral and extracerebral clots following spontaneous cerebral rupture, should be removed, as in traumatic cases, in the hope of shortening the duration of the illness or preventing a fatality. In traumatic cases in which there has been a tear of a normal vessel wall there is within a short time complete occlusion of the vessel with little likelihood of recurrent bleeding, but the possibility of recurrent bleeding in these cases of spontaneous rupture in which the outflow of blood is stayed only by a recent clot makes the early removal of the blood a complex question. The removal of the blood, in some cases at least, must be undertaken only as a means of controlling the more serious symptoms, allowing the patient to go through a tedious course of meningeal irritation or increased intracranial pressure until such time as the clot in the ruptured vessel becomes organized and effectively plugs it. Subarachnoid drainage is useful in the cases in which the blood is washed into the cerebrospinal fluid but should never be undertaken in cases showing evidence of large blood clots. If a clot exists, the patient recovers spontaneously or the symptoms progress, demanding removal of the clot. Superficial localized clots can be removed through a craniotomy, a procedure in many cases contraindicated by the poor general condition of the patient and the possibility of recurrent bleeding, or by aspiration of the blood through a small trephine opening. Aspiration can be accomplished under local anesthesia but must be delayed until there is beginning cyst formation; in the author's cases it has not been followed by further bleeding. If the clot cannot be localized, serious symptoms of increased intracranial pressure may be relieved by a decompression. The author emphasizes that spontaneous cerebral hemorrhage is a common accident and may occur at any age; it must be taken into consideration in the differential diagnosis of a large number of intracranial disorders. Treatment in properly selected cases, especially in young persons, is followed by satisfactory results.

Brain Changes in Endocarditis.—Diamond reports that cerebral lesions in malignant endocarditis are extremely common. Of a consecutive series of thirteen fatal cases, all showed pathologic lesions in the brain even when definite clinical manifestations other than those usually regarded as of septic origin were absent. In some cases, however, the cerebral symptoms dominated the clinical picture. The types of lesion in the brain may be as varied as the clinical picture. They may be inflammatory or degenerative, circumscribed or diffuse, and the forms are frequently combined. Indeed, the lesions of the brain are only a partial manifestation of a general involvement of the central nervous system and of the whole body. They represent reactions of the nerve tissue to the infectious process that underlies malignant endocarditis. Bacteremia is usually present and is of especial interest in regard to its effect on the nerve tissue. Micro-organisms and septic emboli from the thrombo-ulcerative valves of the heart more or less flood the blood stream and become lodged in various organs, including the brain.

Toxic Encephalopathy in Measles.—Ferraro and Scheffer believe that a toxic factor is the basis of the cerebrospinal manifestation occurring in the course of measles, and that if this factor is extremely powerful, all the elements, neuroglia and nerve cells undergo changes dominantly of the degenerative type, while if the intensity of this factor is moderate, the action will be fought in the perivascular areas, thus stimulating the defensive power of microglia cells, which therefore proliferate around the blood vessels.

Action of Certain Drugs on Cerebrospinal Fluid and Blood Pressure.—Loman and Myerson describe experiments in which they demonstrated that epinephrine causes a rise in intracranial pressure, together with a rise of arterial and internal jugular venous pressures. The rise in intracranial pressure is probably due to the sharp rise in arterial pressure, since there is a vasoconstriction of the cerebral blood vessels. Amyl nitrite causes a rise in cerebrospinal fluid pressure with a fall of general arterial pressure and a rise in internal jugular venous pressure. Since amyl nitrite causes a vasodilatation of the blood vessels of the brain, it is believed that the rise in spinal fluid pressure follows the increased brain volume caused by vasodilatation. Solution of pituitary causes a rise in cerebrospinal fluid and internal jugular venous pressures. The arterial pressure drops. It is difficult to explain the rise in cerebrospinal fluid pressure in the case of this drug, since there is a conflict of opinion as to whether the vessels of the brain are dilated or constricted. Histamine causes a sharp rise in cerebrospinal fluid pressure with a moderate to slight drop of arterial pressure and no change in jugular venous pressure, thus forming an exception to the rule that cerebrospinal fluid pressure and intracranial venous pressure are linked together. The explanation may be that this drug has a definite secretory effect on the choroid plexus or that there may be a vasodilatation with an increased flow of blood through the brain, thus increasing the brain volume without increasing the internal jugular venous pressure. Caffeine sodium citrate causes a drop of cerebrospinal fluid pressure with little change in either the internal jugular venous or the general arterial pressure. The explanation may be that the diuretic effect of caffeine, by lessening the blood volume, causes this drop.

Immunity to Exotoxin of Streptococcus Hemolyticus.—Nemhauser calls attention to the fact that since antitoxin administered to persons with scarlet fever does not interfere with the development of antitoxic immunity in convalescence, the fear that no immunity will be developed is not a contraindication to the use of serum in severe cases of scarlet fever Neither does the presence of tonsils seem to be any significant factor in predisposing to scarlet fever

Transmission of Diphtheria Antibodies to Offspring.—Richardson made measurements of the diphtheria antibodies, antibacterial and antitoxic, in the serums of the offspring of guinea-pigs previously immunized with diphtheria filtrate The data showed that diphtheria antibodies of the antibacterial sort as well as antitoxin are transmitted placentally The proportion of antitoxin antibodies to nonantitoxin antibodies found in the serums of the offspring shortly after birth was comparable to that in the serums of their respective mothers The serums of a number of families were studied over periods of sixty or more days following the births, the data of these tests showed that the amount of antibodies originally transferred by the mother is the important factor in determining the duration of the passive immunity of the offspring

Milk-Borne Poliomyelitis.—Rosenow reports a study of an epidemic of acute poliomyelitis at a midwestern college A pleomorphic streptococcus having a peculiar infecting power, specific immunologic properties and characteristic cataphoretic velocity was isolated from the throats and spinal fluid in frank and abortive cases, from the throats of a large proportion of well students and from the milk of healthy cows in the dairy at the time of the epidemic, but not after the epidemic had subsided and not at the time of the epidemic or later from the throats of student volunteers, or from the milk supply at a neighboring, unaffected college The epidemic was traced to raw milk from which large numbers of the "poliomyelitis" streptococci were isolated New cases abruptly ceased to occur after the use of the raw milk was discontinued There occurred a marked reduction of positive skin reactions to the "poliomyelitis" streptococcus during convalescence, and in the well students, especially males, six weeks after the epidemic had subsided, whereas the incidence remained the same in the students at the unaffected college at the time of the epidemic and six weeks later The serum of persons who reacted negatively to intradermal injections of the "poliomyelitis" streptococcus, irrespective of whether they had had poliomyelitis, and the poliomyelitis antistreptococcus serum used in treatment neutralized the toxigenic substance to a greater degree than the serum of persons who reacted positively and the serum of the normal horse The serum from the convalescents and that from persons who had had poliomyelitis a long time before had a more marked specific potential-lowering effect on the "poliomyelitis" streptococcus than the serum of persons who had not had poliomyelitis The poliomyelitis antistreptococcus serum seemingly had a beneficial action in the treatment of the patients

Croupous Pneumonia Caused by Pneumococcus Type I.—Strøm reports that an epidemic of lobar croupous pneumonia in an orphanage was caused by pneumococcus type I Pneumococcus type I was found in the sputums and in cultures from the nose and throat of the patients during illness and up to seventy-three days after the crisis In one case it was found in a culture from the nose and throat four days before the onset of the disease Of the contacts, 33 3 per cent were found to be carriers during the height of the epidemic, and 16 9 per cent two and one-half months later The strains from the patients were more virulent in mice than those from the carriers The disease was more prevalent among the older boys than among the younger ones, presumably because the former represented a more rural population than the latter

Sporotrichosis—Benham and Kesten describe experiments in which they observed that Sporotrichum schenckii produced in the monkey a nodular sporotrichosis simulating the lymphangitic type of infection in man The human disease was transmitted to carnations, in which it produced a bud rot similar to that caused by Sporotrichum poae After living saprophytically or parasitically in plants, Sporotrichum schenckii retained its virulence for animals

Organism Isolated in Atypical Typhoid.—Lazere and Breaks isolated a bacillus from the blood of two children in the same family, who apparently had the same infection, an atypical typhoid Bacteriologically and serologically, this bacillus was intermediate in its characteristics between the typhoid bacillus and the Shiga dysentery bacillus

Surgical Treatment of Pulmonary Tuberculosis—Broga and Welles state that with a skilful operator the operation of pneumolysis is attended with little discomfort or danger to the patient Many distinctly unfavorable pneumothorax cases may be converted into decidedly favorable ones as a result of the marked increase in collapse with resulting closure of cavities Pneumolysis should be resorted to as soon as it is determined that an unfavorable adhesion will stretch no further without undue pressure Delay may allow a thin-walled cavity to develop heavy walls and become highly resistant to closure, even after separation of the adhesions Also, continued stretching may cause adhesions to become tough and tendinous.

Development of fluid is to be expected. This is usually slight in amount and seldom interferes with the progress of the case. Danger from hemorrhage may be greatly reduced by slow, careful progress, by avoidance of thick adhesions, and by the use of a low dull-red cauterizing heat. Serous oozing is to be expected and is of no consequence. Only thin, string or sheet-like adhesions are suitable for cauterization. Short or thick ones may contain sizable blood vessels or even portions of lung tissue or extensions of pulmonary cavities. Also, the proximity of the cautery to the pleura together with an extensive cauterized surface may cause much annoying pleurisy.

Intracranial Injuries of Fetus.—Adair enumerates the methods of prevention of brain injuries in infants thus: (1) Prenatal care by which attempts are made to bring the patient to term with the fetus in the proper position, and predetermining so far as possible the appropriate method of delivery; (2) proper management during labor, with conservative conduct of the first stage, preservation of the membranes, the prevention of violent labors by the use of uterine sedatives and anesthetics if necessary, the avoidance of too prolonged pressure on the fetal head in the birth canal or on the perineum, the recognition of signs of fetal distress and the completion of the delivery when conditions are favorable; (3) avoidance of undue occipital depression by its pressure against the pubic arch especially by vigorous attempts to protect the perineum (also avoidance of delivering the aftercoming head in breech extraction and following version by using the occipital bone as the fulcrum of a lever in rotating and delivering the head over the perineum); (4) the restriction of the use of artificial means of delivery, to strict indications on the part of the mother or fetus when favorable conditions are present; (5) the selection of the proper time and method for artificial delivery and the use of good technic, and (6) the recognition of the fact that many of the infants which appear asphyxiated and do not breathe promptly or properly are in many instances traumatized and should be treated gently and not by strenuous attempts at stimulating respiration.

Acute Hemorrhagic Mastoiditis.—Smith calls attention to the fact that acute hemorrhagic mastoiditis is a type in which the pathologic process is limited to the interior of the blood vessels, where septic thrombi are formed. It is characterized by a condition of sepsis with prostration and high temperature. The blood shows a steady reduction in the hemoglobin and red blood cells. The roentgenogram is negative. The treatment is always surgical. Because intracranial complications, especially lateral sinus thrombosis, tend to occur early, the operation should be performed as soon as the diagnosis is made.

Cancer of Genito-Urinary Organs.—Dean considers the use of radium and the roentgen rays an important adjunct to surgery in the management of renal adenosarcoma and adenocarcinoma. It is probable that bladder cancers can be controlled more effectively with interstitial irradiation than by surgery alone. After irradiation the operative mortality is lower and the end-results are better. About 15 per cent of prostate cancer can be controlled by irradiation. There is a field of usefulness for irradiation in the treatment of superficial penis cancer. Beyond this, irradiation is a valuable adjunct to surgery. The treatment of teratoma testis by irradiation is so successful that surgery should be discarded except for the removal of an irradiated testis.

Invaginated Meckel's Diverticulum. — According to McCann, a survey of the literature reveals that simple inversion of a Meckel's diverticulum is a rare phenomenon He presents a review of ten cases reported in the literature, and a case of inversion in which he operated. Persistent diverticula, which are found in 2 per cent of necropsies, give rise to diverse complications. Intestinal obstruction is the most common and is produced frequently by intussusception of the intestine secondary to invagination of a diverticulum. This is the causative mechanism in 7 per cent of obstructing intussusceptions and carries an operative mortality of from 50 to 60 per cent. Simple uncomplicated inversion is rare, and in the author's case the serious complication of intussusception was probably averted by the paramesenteric location of the structure, and fortuitous surgical intervention. Chronic inflammation had agglutinated the serosal surfaces at the base of this inverted diverticulum, forming a polypus-like sac within the lumen of the ileum, which produced symptoms of partial obstruction. This case presents proof of the hypothesis long held that some polypi of the small intestine take origin from an inverted Meckel's diverticulum.

Irradiation in Treatment of Hyperthyroidism.—Pfahler states that a review of the literature shows a progressively increasing recognition of the value of both roentgen rays and radium in the treatment of thyrotoxicosis. The results obtained by irradiation are equal to those obtained by operation, with less shock or risk to the patient. The basal metabolism can be gradually reduced to normal, and there is practically no danger of producing hypothyroidism. Tetany has not developed in any of the author's cases. One can assume that no harm has been done to the normal parathyroid. The author believes that not surgery, nor irradiation, nor medication can be depended on to cure all cases and no one is so much superior that it can be recommended to the exclusion of the other two. No definite rules can be laid down at present for the selection of the method for the individual patient. It is the general opinion of radiologists that in all cases which are not seriously involved by mechanical pressure, or so acute as to make delay of a month dangerous, the patients should be treated by irradiation. Irradiation and every valuable method of medication can certainly be combined to advantage. If there is no definite improvement after two or three months, surgery can still be used. The delay that always precedes operation can be used to advantage in this manner. When irradiation fails, surgery can still be used; when surgery fails, irradiation can be used. Medication and the advice of the internist are of value in all cases, but there will remain a small number in which all methods will fail.

Diagnostic Pneumothorax.—According to the Faulkners, diagnostic pneumothorax is safe, relatively easy to perform, and does not aggravate the patient's condition. It is of definite value in the differentiation of parietal pleural tumors from those within the lung and mediastinum. It furnishes essential information in the selection of chest cases for operation; and it indicates the type of anesthesia and surgical approach that will be best fitted to the individual case.

Ptosis and Torsion of Gallbladder.—According to Meeker and Lisenby, cholecystoptosis results primarily from congenital anomalous attachments of the gallbladder. Further pathologic changes are usually dependent on ptosis. The most serious complication that can happen to a floating gallbladder is that of complete torsion. A case of torsion observed by the authors illustrates the main features of this condition exemplified in the group of twenty-five reported cases: (1) previous history of "bilious" attacks; (2) the failure of preoperative diagnosis; (3) the age and sex, elderly females; (4) the sudden onset and picture of acute condition of the abdomen; (5) the gross pathology, a greatly enlarged freely floating pedicled gallbladder of purplish black color, thickened edematous walls, content of bloody bile and clots and no stones present, and (6) easy cholecystectomy with complete recovery.

Blood Picture in Sickle Cell Anemia.—Sixty-four cases of sickle cell anemia reported in the literature and ten cases observed in Memphis are analyzed by Diggs in regard to the blood picture. The characteristic features of the blood picture in active sickle cell anemia are (1) the presence of sickled cells in moist preparations; (2) signs of red blood cell destruction (poikilocytosis, degenerating forms, microcytes, increased serum bilirubin, negative direct van den Bergh reaction and positive indirect reaction; urobilinuria, phagocytosis of erythrocytes by large mononuclears), and (3) signs of increased regenerative activity on the part of the bone marrow (megaloblasts, intermediary forms, nucleated red blood cells, nuclear fragments of all types, diffuse basophilia, macrocytes, increased reticulocytes, leukocytosis with a shift right and left, increased platelets). Sickling without anemia, hemolytic anemia without sickling, or secondary anemia in association with the sickle cell trait are to be distinguished from true sickle cell anemia. Typical sickled cells, although striking and unmistakable in fixed smears and fresh moist preparations from some cases, are the exception rather than the rule. The average red blood cell in sickle cell anemia is smaller than normal. The cell volume is decreased out of proportion to the decrease in the red blood cell count and hemoglobin. The color index is variable but usually below 1. The erythrocytes in sickle cell anemia are more resistant to hypotonic solutions of sodium chloride than normal.

Ultraviolet Treatment of Miners' Nystagmus.—The lamp O'Sullivan uses in the treatment of miners' nystagmus is the quartz mercury vapor type, in preference to the carbon arc. The patient starts with three minutes of exposure, at 1 meter, increasing daily up to five minutes, and later to fifteen minutes, for a period of five or six weeks if necessary. The first sign the author has observed, when carrying out treatment, and which encouraged him to persevere, was that in all cases the conjunctival hyperemia observed in most cases of early miners' nystagmus cleared up very quickly. In nearly all cases under treatment, the patients were back at work within eight weeks, with little or no symptoms or physical signs The ultraviolet irradiation was usually given as a general body bath. A few patients were treated by short local exposures, the patient wearing no goggles but keeping the eyes closed. Ultraviolet irradiation alone will not give immediate benefit, so long as some underlying focus of infection is allowed to persist. But in cooperation with other remedial measures, it exerts a definite curative influence on miners' nystagmus The author reports six cases of miners' nystagmus treated successfully by ultraviolet irradiation.

Treatment of Chronic Myeloid Leukemia.—In the treatment of chronic myeloid leukemia, Piney and Riach practice preliminary roentgen exposure of the long bones, followed by irradiation of the spleen This produces an even greater fall of abnormal cells than is the case if the spleen alone is treated. It is usual to treat persons with chronic leukemic myelosis until the blood picture is fairly satisfactory and the patient is feeling well; then it is often thought to be sufficient to instruct the patient to report again if at any time he does not feel in good health. It is generally found that, when the patient returns complaining of malaise, the characters of the blood picture have gravely deteriorated and further treatment is essential. The authors were particularly fortunate in two of their cases, since it was possible to examine the patients' blood at least once a week. It was found that the leukocytes, and particularly the abnormal forms, gradually rise from the level to which they had been reduced by treatment, and that this increase continues slowly but persistently for several weeks, or even months, before the patient feels at all unwell. Furthermore, during this period of deterioration of the blood picture, no ordinary clinical signs of the progress of the malady can be detected. When the number of leukocytes rose to 60,000 or 70,000 per cubic millimeter the treatment was repeated, even though the patient made no complaint of ill health. The literature contains many statements to the effect that each relapse is more difficult to treat satisfactorily than was the preceding attack. This is probably due to the excessively long intervals between the courses of treatment. This, of course, is inevitable if irradiation is undertaken only when the patient notices some signs of the disease. The authors contend that it is essential to observe the blood picture at very short intervals throughout the patient's life, and to undertake treatment in early hematologic relapses before the clinical relapse has manifested itself.

*Genesis of Blood Platelets C H Watson —p 311
Treatment of Pernicious Anemia with Campolon R M Murray-Lyon. —p 328

Blood and Tissue Reactions.—Harvey and Hamilton describe experiments in which they demonstrated that there is not a large error in making a single leukocyte total count provided the necessary precautions are taken The differential cell count on a well made, and to a surprising extent on an ill made, film is significantly valid for diagnostic purposes. There is evidence of long-wave diurnal oscillation of leukocyte numbers and proportions, but not sufficient evidence of a superimposed periodic short-wave type of fluctuation. All sorts of factors, such as sleep, posture, heat and cold, muscular exercise, locality of examination, digestion and simple ingestion may be regarded as traumas and may produce leukocytic variation of greater or less duration and may combine to enhance or to mask the variation due to any one factor singly.

Genesis of Blood Platelets.—According to Watson, the reticulocytes are the least prone to fragmentation of all the erythrocytes The erythrocytes make their exit from the circulating blood mainly by a process of fragmentation By a variety of processes, which cause partial laking, the author shows that the erythrocytes of rabbits which have been damaged in vitro by the injection of phenylhydrazine contain a granular material similar in every respect to the granular material of platelets He shows that the damaged erythrocytes have a marked tendency to fragment, also that under certain conditions the fragments have a basophilic ground-substance in which is variously distributed pink-staining granular material The fragments of effete or damaged erythrocytes correspond in every detail to the bodies known as blood platelets

*Indications for Radical Operation in Chronic Middle Ear Suppuration S H Mygind —p 297
*Some Postoperative Results of Radical Mastoid Operation in Children Postoperative Otorrhea N Asherson —p 317

Chronic Middle Ear Suppuration.—Mygind believes that the greatest difficulty in the treatment of chronic middle ear suppuration lies in the treatment of children, in whom radical operation, as also with unintelligent patients, generally gives unsatisfactory results. This also holds good for the simple resection or preferably the Bárány partial resection, which, when obliged to operate, one often has to make do. In such cases it is not enough to provide only for conventional adenotomy. Children should be submitted also to comprehensive general medical examination. Their hemoglobin, their Wassermann reaction, their Pirquet reaction, their rickets, their family predisposition to ear trouble, catarrhs and tuberculosis, the state of their homes and their diet must all be investigated, and all energy directed in the right direction in order to invigorate their general well being. This demands much labor and a lengthy stay in the hospital, often accompanied by Finsen light treatment, baths and open air treatment. But it is here that action must be taken, for it is often in childhood *that middle ear disease begins its fateful course even if it is* much later on that it first shows itself in earnest, often as a serious inconvenience, sometimes as invalidism and, in certain, generally sudden and dramatic cases, terminating fatally.

Postoperative Otorrhea.—Asherson tabulates the results in 100 consecutive cases of the radical mastoid operation and conservative mastoid operation in children. In a purely tympanic infection, the mastoid being healed, with no granulations in the tympanum, ionization with zinc sulphate will effect a rapid cure. Attention to the nasopharynx is essential. Thus adenoids, septic tonsils and sinusitis require attention. This is an essential part of the treatment. When granulations occur in the tympanum they should be cauterized with 50 per cent solution of silver nitrate, and after a few days 1 per cent iodine powder should be insufflated regularly. Hypertrophied granulations or polypi require removal by scraping, snaring or curetting. The base should be cauterized with silver nitrate. This applies to the mastoid part of the excavation also. If there is much bone disease still present, or any atresia of the meatus present, further treatment by operation is indicated and the infective bone disease should be eradicated. Among the accessory methods to be attempted in highly resistant cases are heliotherapy, ionization with very weak solution of silver nitrate or, after thorough cleansing, packing the cavity with strips of gauze impregnated with bismuth iodoform paraffin paste. The discharge persisting after the radical mastoid operation is usually an extremely chronic one, and reaction to treatment is disappointing in a large majority of cases, and further operation is usually called for unless the site of origin is localized to one or two definite spots.

Prevention and Treatment of Industrial Rheumatism.—Ray calls attention to the fact that in dealing with industrial rheumatism it is of the greatest importance that patients should be able to obtain treatment at the earliest possible moment after the first signs of the malady. If, in consequence of this, time has to be lost in attending an institution, treatment will be deferred with the grave risk of complete incapacity. Few complaints show better results than fibrositis or muscular rheumatism if treated early enough. In establishing the clinic for rheumatism, one of the main objects of the British Red Cross Society was the provision of evening treatment for men and women after working hours. Analysis of the social service records of those patients who have finished their treatment during the year 1931 shows that 40 per cent of the 1,012 men and 51 per cent of 1,463 women remained at work during the period they were attending the clinic. In industrial rheumatism, preventive measures are mainly applicable to the conditions of employment. Dampness and chills are a fruitful source of much invalidity from muscular rheumatism and fibrositis. Workers who are exposed to continual wetting and subsequent chilling should be provided with adequate drying rooms and opportunities for changing into dry clothing. In case of joint disabilities, so many of which are connected with certain trades, an endeavor should be made, when practical, to afford a change of occupation when signs of arthritis appear. It is fully recognized that in the majority of instances this is impossible. Timely treatment by physical methods may do much to prevent any further development, but it must be in the earliest stages. Once bony changes have taken place, little in the way of a permanent cure can be effected. As regards the individual himself, the ordinary rules of hygiene should be strictly followed. Septic teeth and tonsils should be dealt with. In the type of patient who is predisposed to rheumatism, much may be done by the use of baths to tone up the skin and render it less sensitive.

*Cerebrospinal Fluid Pressures in Syphilis. T. F. Hewer.—p. 1042.

Appendicitis.—Berry does not find any evidence for the statements that appendicitis is more common than it used to be and that the type of infection has become more virulent, and he does not believe that they are true. That the disease is recognized and diagnosed more frequently, and that active treatment is adopted far more often, there can of course be no shadow of doubt. That deaths are more common now than formerly is apparently an undoubted fact. The author believes that there should be introduced a little more sanity into the present-day treatment of acute appendicitis, a little more discrimination and judgment in the choice of operation and when and how it should be performed when it is really necessary, a little less reliance on the hard-and-fast rule, adopted by so many, of operating at any and all stages—a rule so easy to follow but often so disastrous to the patient. He has spent half a century in watching and studying appendicitis in all its various moods and forms. He has seen nearly every form of treatment from the simplest to the most heroic. Looking around him, he is inclined to say that the prevalent surgical treatment of appendicitis, though still holding the position of an idol, is an idol whose pedestal is beginning to totter.

Mode of Action of Vitamin D.—Investigations made by Harris on hypervitaminosis have substantiated the theory that the characteristic mode of action of vitamin D is to permit an increased "net absorption" of calcium and/or phosphate from the intestine, tending to raise the level of the blood calcium and/or phosphate: the latter rise automatically brings about increased calcification in sites provided with the "bone" or "calcifying" enzyme, phosphatase. This action is apparent whether the vitamin is fed in suboptimal amounts, in doses approaching the optimum, or in moderate excess. Hypervitaminosis thus stands in logical contrast with rickets (hypovitaminosis or avitaminosis). In the latter there is deficient net absorption of calcium and/or phosphate, hence hypocalcemia and/or hyperphosphatemia, and resulting insufficient calcification; while in hypervitaminosis there is a potential increase in net absorption, hypercalcemia and/or hyperphosphatemia, and excessive calcification in sites such as the growing end of the bone, in teeth, and also in certain soft tissues such as the kidney and aorta, which are also richly provided with the "bone" enzyme. The indiscriminate use of parathyroid extract clinically for cases of suspected calcium deficiency is to be deprecated, most definitely in such conditions as infantile tetany, osteomalacia and late rickets; for although it will succeed in raising a low blood calcium, it merely aggravates the underlying metabolic error causing loss of minerals to the body, and still further depleting the already impoverished bones. Vitamin D, on the contrary, rectifies hypocalcemia (or hypophosphatemia) by ensuring an adequate utilization of the food calcium (and/or phosphorus). The ill effects in hypervitaminosis are the same in man as in experimental animals. Clinical experience shows that for the human being the toxic overdose of viosterol is not far removed from the optimal (not "minimal") curative dose. The correct dosage should therefore be strictly adhered to.

Cerebrospinal Fluid Pressures in Syphilis.—In a series of 313 cases of syphilis in which he made routine examinations of the cerebrospinal fluid, Hewer found that hypertension was the least common abnormality and that there was no apparent relation between the degree of pathologic change and the pressure of the fluid. In the series there were twenty cases of clinical neurosyphilis. Ninety-two presented pathologic fluids, but only five showed pressures in excess of 20 cm. of fluid, and one of these was certainly due to congestive heart failure. These figures contrast strikingly with those presented by other authors and are in entire disagreement with the constantly repeated textbook opinion that hypertension is one of the earliest signs of syphilitic involvement of the central nervous system.

Eye Disease and General Medicine.—Clarke believes that one of the most subtle associations, perhaps the commonest for harm between the eye and the body, is revealed in eyestrain. Every one knows that headaches may be caused by eyestrain, but even now it is not generally recognized how many complaints may owe their origin to it. Ocular migraine, dyspepsia, insomnia, general lassitude or malaise may be entirely due to eyestrain—or eyestrain may be the chief cause. The reason this is so subtle is that more often than not the eyes are not suspected. Vision is good and the patient is quite unaware that this good vision is obtained at a big expense of nervous energy. Small errors of astigmatism and anisometropia can be unconsciously corrected, and this means a constant drain on the nervous energy; impulses are passing from the brain to the ciliary muscle during all the waking hours. In the robust and the young, this may not have any apparent harmful effect; but in those who are weakly or who have a delicate nerve organization or whose "nerve balance" is easily upset, this constant drain may produce all sorts of symptoms. It must be remembered also that, in addition, this eyestrain produces reflex irritation and loss of resisting power both locally and generally, and lowered vitality.

Iritis.—Duke-Elder calls attention to the fact that to a large extent the term "iritis" is a misnomer. Anatomists have long been accustomed to divide the uveal tract into three parts (the iris, the ciliary body and the choroid) and following them clinicians have spoken of iritis, cyclitis and choroiditis. It must be remembered, however, that these descriptive terms tend to convey an impression of localization which is rarely justified in the spheres of physiology or pathology. The eye is limited by a tough and relatively impermeable sclerocorneal coat, and within this coat all the tissues are bathed with the common intra-ocular fluid, in which a very free diffusion of toxic materials is permitted, so that the tendency is for the eye to be involved and respond as a whole even to an isolated lesion. Moreover, the vascular arrangements, although terminally divided into an anterior and a posterior system, are richly supplied with anastomoses, and the nerve supply is identical, so that both in its normal metabolism and in the derangements of its functions the uveal tract tends to act as a unified whole, wherein if one part becomes inflamed, the remainder tends to suffer simultaneously. Probably to a large extent depending on the arrangement of the blood vessels, however, inflammatory disturbances do tend to localize themselves as an anterior or posterior uveitis, and in the former category, although there is probably never an iritis without a cyclitis, the large group of cases in which an inflammation of the iris dominates the clinical picture justifies the use of the term iritis. The greatest interest and most important aspect of cases of iritis are their etiology, for on this hinges their prevention, their rational treatment, and the undertaking of precautions against recurrences which too frequently bring disasters in their train. Unfortunately the etiology of iritis is a question about which much is obscure. At the commencement, two types may be differentiated: (1) those relatively rare and obvious cases wherein an infection is introduced into the eye by a perforating wound or ulcer, and (2) the great majority of cases, wherein the causative agent enters through the blood stream. In the latter group of cases the inflammation may be set up by the entrance either of micro-organisms or of toxic materials into the eye. In a small minority of cases in which actual tuberculosis or gummatous nodules are present, the type and method of infection is obvious; but the average case of iritis presents a nondescript, nonspecific clinical picture and can only be assessed as a member of a heterogeneous group in which scientific classification is as yet quite impossible.

Cataract.—According to Elliot, the earlier a mature cataract is operated on the better. The patients are usually elderly, and though even extreme old age does not constitute a bar to the operation, every year younger is an advantage at a time of life when deterioration is much more rapid than in the earlier decades. No patient should be allowed to drop his ordinary activities and to sink into listlessness. Once a patient reaches the stage when he can no longer get about comfortably, or when he cannot read, write and carry on his usual occupations, he should be operated on without delay. To the skilled operator, immaturity of cataract presents no real difficulty. The fact that a cataract is commencing in the opposite eye is an added reason for early operation on the first one. The exact time for operation demands careful thought. The guiding principle is to get the first eye operated on and to give it time to become strong and useful before the second becomes too blind to be serviceable. This necessitates operating on immature cataracts in those cases in which the second eye follows the first after a short interval. Though a patient has a good result in one eye, the second should be operated on if cataractous, for the following reasons: 1. The sight of the first eye may be lost by injury, retinal hemorrhage, glaucoma, or other dangers common to the old; when sight is concerned, no risks should be taken and every vestige should be conserved; therefore, the margin of safety must be made as wide as possible. 2. Binocular vision is much better than monocular, and much safer. 3. The longer the operation is put off, the greater the age of the patient, and, therefore, the greater the risks of trouble.

Chronic Coli-Bacillemia.—Desgeorges states that chronic coli-bacillosis is generally looked on as a disease which is more troublesome than serious. By reason of its refractoriness, the ease with which it recurs, and the multiplicity of the disturbances to which it gives rise, the author feels justified in asserting that it is, on the contrary, a formidable disease. It is serious because it plays a foremost part in the causation of pathologic conditions as difficult to cure as pyelitis and chronic cystitis, and as painful and subject to complications as cholecystitis and cholelithiasis. It is serious because of its frequent disastrous effects on the general health and the nervous system.

Diphtheria Prophylactics.—From the evidence in the literature and from experiments at Greenwich Hospital School, Dudley believes that three fortnightly doses of a reliable toxoid, if given to only half the population under 10 years of age, would reduce the incidence and mortality from diphtheria to an extent that would make active immunization a sound financial investment, besides being of benefit to the public health

M. Roberts Field Library

If as many as 80 or 90 per cent of children under 10 could be maintained Schick immune, he believes that, for practical purposes, diphtheria would vanish within five years.

Spontaneous Overbreathing Tetany.—McCance calls attention to the fact that certain persons are peculiarly susceptible to the changes of reaction brought about by overbreathing. Tetany may develop in these persons with scarcely noticeable overbreathing and before any definite chemical change can be detected. Investigations on two such persons are described. Many of the cases of so-called sporadic tetany in adults may be of this type. Diagnosis is easily confirmed by making the patient overbreathe. This procedure is harmless and demonstrates at once to the subject the cause of the attacks and how to avoid them. Experiments performed by the author with epinephrine in one case suggest that this drug has no direct action in producing tetany, but that it may do so by stimulating hyperventilation. Associated with the tetany, one case showed a reduction of the T waves in the first and second leads of the electrocardiogram.

Mobility of Abdominal Viscera.—Barclay records a study of the effect of posture and of forced respiration on the abdominal viscera. Composite pictures are reproduced showing the displacements and distortions. These indicate that in normal subjects the abdominal organs are not fixed and that they have a wider range of movement, in relation both to the abdominal wall and to each other, than might be expected. The illustrations record the mobility and indicate the "fluid" character of the anatomy of the abdominal viscera.

Electrocardiogram in Diphtheria.—Alstead states that the electrocardiograph is a valuable means of estimating the severity of diphtheritic myocarditis and the only means of accurate diagnosis of conductive lesions in the majority of cases. Though a large proportion of cases in which the patient has mild myocarditis are undetected by clinical methods, such cases become comparatively rare in the moderate and severe types of diphtheria. Hence for practical purposes the character of the heart sounds is usually a sufficiently accurate guide to the state of the myocardium. The clinical signs most closely related to the electrocardiographic observations are those dependent on cardiac function; e. g., response to effort and the trend of the pulse rate. The significance of persistently "abnormal" heart sounds can be safely estimated by the electrocardiogram and the patient's response to effort, considered together. Of the various physical signs in the heart taken to indicate myocarditis in diphtheria, the most valuable as confirmed by simultaneous electrocardiographic records are: (1) progressive softening of the first heart sound at all areas, especially the mitral and aortic areas; (2) the character of the cardiac impulse at the apex and movement of the apex beat to a position farther away from the midline, and (3) splitting of the first mitral sound producing a triple rhythm. Serial electrocardiographic records show that, in a considerable proportion of cases, with the onset of diphtheritic paralyses there is a simultaneous relapse in the condition of the heart. This fact is much less frequently observed when clinical methods alone are employed. The severity of the cardiac lesion is usually proportional to the severity of the toxemia when specific treatment is commenced. There are, however, cases in which neither the clinical nor the electrocardiographic abnormalities are sufficient to account for the state of impending circulatory collapse that is often seen in diphtheria. Although gross degeneration of the heart muscle and specialized conducting system are frequently shown by the electrocardiograph during diphtheria, these lesions are mostly transient. Complete heart block is by far the commonest lesion associated with circulatory collapse ending fatally, but complete block is probably only a contributory factor in a condition characterized by widespread changes in the circulatory system. Fifteen fatal cases are classified by the author according to the "early" and "late" types described by Schwentker and Noel. Except in the event of complete heart block, no reliance can be placed on the electrocardiographic observations in diphtheria in assessing prognosis.

Treatment of Obesity.—Lyon and Dunlop studied the reduction in weight in thirty-five cases of different types of obesity. All the subjects, including marked endocrine cases, lost weight while dieting. It was found that the rate of weight loss bears a definite relation to the caloric value of the diet: the smaller the diet, the more the loss. The rate of loss is greatest at first and decreases as the diet is continued. If the total caloric intake is kept constant at 1,000, the weight loss is greatest when the carbohydrate of the diet is low. It was found that 9 grains (0.6 Gm.) of thyroid extract is required in order to produce a loss of weight equal to that caused by the standard 1,000 calory diet. The effect of the thyroid is proportionate to the dose given. The basal metabolic rate for the series of cases was usually within normal range on admission. The rate usually fell during the period of undernutrition and was raised about 20 points during the administration of thyroid extract. The loss of weight when the patients were taking low diets appears to be due to removal of fat and water from the body, but when thyroid is given the utilization of fat represents a smaller fraction of the weight loss, while the proportion of water removed from the body is greater, and some of the loss may be due to a negative protein balance.

*Clinical Forms of Rat-Bite Fever. Costedoat.—p. 505.

Clinical Forms of Rat-Bite Fever.—Costedoat describes the three principal forms assumed by rat-bite fever in European climates. The common form starts with an attack of fever about fifteen days after the rat-bite is received. At the same time the region of the bite (usually the hand) becomes inflamed and a lymphangitis ending in epitrochlear or axillary adenitis develops. An eruption of red macules or papules of lentil size chiefly on the affected members, but sometimes on the whole body, accompanies the febrile attack. The fever recedes suddenly after about three days. These febrile attacks, accompanied by eruption and inflammation, recur at intervals of a few days for months or a year unless specific treatment is given. Local symptoms sometimes precede but never follow the rise in temperature. The eruption may not appear until the fourth attack and is of variable nature; sometimes it appears as papules, sometimes it resembles the erythema of measles and rarely it is petechial. The muscular pain is severe and does not disappear entirely during the remissions. There is a moderate leukocytosis and the proportion of polymorphonuclear cells is sometimes increased to 95 per cent. The disease is easily differentiated from common local infection, erysipelas, syphilis, measles and so forth. Positive diagnosis is easily made when all symptoms exist, but valuable aid is furnished by etiology, therapeutic test and laboratory examination. A rat-bite is necessary for the development of the disease. Immediate response to an injection of neoarsphenamine is a diagnostic aid, although cure requires a long series of injections. The best laboratory procedure for isolating the spirochete of rat-bite fever is subcutaneous inoculation of 2 cc. of the patient's blood (taken during one of the first febrile attacks) into a mouse. The spirochetes can be recovered from the blood and organs of the animal in from one to four weeks. A localized form of rat-bite fever in which the eruption or fever or both may be absent has been encountered. Less rare than the localized form is the septicemic form in which local manifestations are slight or lacking while the general symptoms are those of the common form. The septicemic form may resemble an eruptive fever or it may be characterized by the intensity of the pains or, as shown in a case report, a period of recurrent fever without skin lesions may be followed by a sort of erysipelas of the head and upper limbs. Differentiation of rat-bite fever without eruption from relapsing fever, icterogenic spirochetosis and other recurrent fevers is discussed.

Calcium Chloride in Cardiac Disturbances. S. Vialard.—p. 523.

Staphylococcic Pott's Disease (Staphylococcic Spondylitis) in Adults.—Carnot reports and discusses two cases of staphylococcic spondylitis in middle-aged men. The condition so strongly resembled Pott's disease that he designates it by that name in the title. In the first case, after a long series of staphylococcic manifestations, certain osseous localizations persisted with prolonged suppuration of one finger and the sternum and above all severe destruction of the bodies of several thoracic vertebrae, resulting in kyphosis. In the second case, multiple staphylococcic furuncles over a long period were followed by a staphylococcemia, which was apparently cured by bacteriophage but was followed soon afterward by vertebral spondylitis with destruction of the anterior part of the body of the eleventh and twelfth thoracic vertebrae with gibbosity and radicular pains and a congestive abscess in the lumbar region. The case terminated fatally, as frequently happens in staphylococcic spondylitis affecting the vertebral bodies. Chronic staphylococcic spondylitis in mature persons, evolving like Pott's disease, is much less well known than the acute vertebral osteomyelitis of childhood or adolescence. Clinically it is characterized sometimes by suppuration, sometimes by nervous disturbances, and sometimes by gibbosity. The abscess formation which occurs in most cases is described; it may be extrarachidian or intrarachidian. The nervous disturbances may appear as pseudorheumatic pains, lumbago, or vertebral rheumatism. Some cases present the form called vertebral epiphysitis of adult growth; sometimes spinal cord lesions occur. The principal symptom, gibbosity, often reminding one of Pott's disease, may develop suddenly or gradually. It occurs only in spondylitis of the vertebral bodies; spondylitis of the lamina does not produce it. The author says the etiology of chronic staphylococcic spondylitis with its syndrome of abscesses, radiating rachidian pain and gibbosity often cannot be established even by roentgenography; an anamnesis of multiple staphylococcias or the finding of staphylococci in pus from an abscess is necessary to make a definite diagnosis. Because of the prolonged evolution that often characterizes this disease, one always feels some uneasiness for the future despite immobilization, surgery and vaccines.

*Angina Pectoris Due to Anaphylactic Shock. A. Dumas.—p. 889.

Angina Pectoris Due to Anaphylactic Shock.—Dumas thinks that anaphylactic shock may be added to the list of conditions, such as effort and emotion, productive of the coronary spasm that causes an attack of angina pectoris. He does not think that the shock alone causes the disease, but the coronary lesion is not sufficient to explain the spasmodic nature of the disease and a condition productive of spasm is necessary to bring on the attack. In anaphylactic shock there is a sudden drop in arterial tension, which in persons whose intramyocardial circulation is difficult, because of a more or less discrete coronary lesion, may explain an attack of angina. The author reports two cases of angina pectoris in which the anginal attacks appeared to be linked to digestive hemoclasia in individuals predisposed by a more or less marked hepatic insufficiency. In cases of acute coronary disease the coronary thrombosis or coronary inflammation is sufficient to cause attacks of angina without intervention of a spasm. It is rather in the frequent chronic coronary inflammation of atheromatous nature sometimes discovered at necropsy in persons who never experienced attacks of angina pectoris that spasm plays an important part. In these cases the spasm alone may be considered responsible for the disease, because in the absence of spasm the anginal attack might not occur despite the coronary atheroma. Simple alimentary prescriptions based on a precise interrogation and minute observation may protect the patient from the dreaded attacks.

Semaine des Hôpitaux de Paris

8: 311-342 (May 31) 1932

Syphilis and the Renaissance. Laignel-Lavastine.—p. 311.
*Mesenteric Cysts in Nurslings. A. Martin.—p. 323.

Acute Appendicitis in Children. J. Armingeat.—p. 332.
Acute Osteomyelitis of Pubis: Case. H. Reboul.—p. 335.

Mesenteric Cysts in Nurslings.—Martin reports a case of cystic lymphangioma of the mesentery in a child, aged 18 months. In this case the cystic fluid, which may be chylous, serous, hemorrhagic or purulent in lymphangiomas, was clear and pale yellow. The classic symptoms are signs of compression, gastric and intestinal disturbances, vomiting, diarrhea in some cases, constipation in others and sometimes subocclusion. There is an increase in the volume of the abdomen. Percussion may give variable signs. The complications in these cases are due to increase in volume, causing disorders due to compression, suppuration and rupture of the cyst, which may occur without infectious phenomena and lead to serous or chylous peritonitis. Diagnosis, the author thinks, is always difficult. Theoretically the mesenteric cyst is recognized by its median topography, lateral mobility and incomplete and variable dulness on percussion, but in practice the diagnosis is never made. In the case reported the tumor was in the left hypochondrium; it was not movable in a transverse direction, this being characteristic of the retroperitoneal cyst, which is so firmly attached by its pedicle and lumbar implantation as to be immobile; the percussion sound was dull. In discussing treatment, the author counsels against puncture. He was able to split this tumor and accomplish a complete extirpation avoiding the mesenteric vessels, as the tumor was well isolated and there was no inflammation. Frequently, in attempting total removal of the cyst, one risks injury to the mesenteric arteries or veins. One should perform an operation that produces less shock. Marsupialization of the cyst may have to be done; cure by this method is slower, but one avoids operative failures. One should not try to remove an inextirpable cyst; one should rather limit oneself to partial resection.

*Gastroptosis: Surgical Treatment. A. Jentzer.—p. 335.
Chronic Maxillary Sinusitis. J. Feuz.—p. 347.
Treatment of Cardiac Insufficiencies. E. Bauer.—p. 355.

Surgical Treatment of Gastroptosis.—Jentzer says that ptosis of the stomach may exist independently of other pathologic changes but that it is almost always accompanied by dilatation and atonicity. Lesions of chronic gastritis are habitual in gastroptosis and sometimes more serious disorders, such as cancer, ulcer and biloculation, exist. While gastroptosis may exist alone, it is often part of a complex syndrome, owing to ptosis of most of the abdominal organs. Among the factors favoring the development of gastroptosis are congenital predisposition, dietetic and therapeutic errors, infectious diseases, compression of the epigastric region, loss of weight, and pregnancy. Several theories of pathogenesis are discussed. The subjective gastric symptoms are variable: sensations of fulness after eating, loss of appetite and so on. In the phase of active dilatation with hypertrophy, hunger pangs are felt. Other symptoms are clapotage, frequent eructations, sometimes vomiting, constipation, cardiopulmonary disturbances, nervous disturbances, and malnutrition. Diagnosis is aided by insufflation, roentgenoscopy and intubation. It is important to differentiate between a true pyloric obstruction and primary gastroptosis. For surgical therapy the author recommends Lambret's operation, which consists in suspending the stomach at the level of the greater curvature. Lambret uses a strip of aponeurosis taken from the left side of the left abdominal rectus, pediculated at its upper portion, introduced into the abdomen between two ribs, and fastened to the entire length of the greater curvature and sutured at its free end to the round ligament at the point where it separates from the liver. The author uses dead tendons instead of an aponeurotic strip for the suspension because it shortens the duration of the operation, diminishes the shock, and avoids lateral cicatrices, postoperative complications and finally the partial destruction of the abdominal wall. The aponeurotic band and the tendon do not appear to be resorbed, but if this should happen it would not be very serious as the stomach would have had time to retract and regain its tonicity. The author hopes this operation will replace the use of abdominal straps, which provoke atrophy of the abdominal muscles. Lambert's operation is physiologic; it does not act from one day to the next but progressively without touching the mucosa, and, while it does not always cure the disorder, it cannot harm the patient.

Procedure in Overflow of Pus into Bronchial Tubes Following Perforation of Pleural Empyema. W. Dobrzaniecki.—p. 501.

Tonsillitis Masking Tuberculosis.—Schmid points out that it is generally known that tonsillitis may precede the first manifestation of a tuberculosis. However, that this is considered either as an incidental concurrence or that the tonsillitis is thought to be the factor that led to the manifestation of the tuberculosis he does not accept as true for all cases. He admits that either may occasionally be true, but he thinks that in the majority of cases the relationship between the pharyngeal symptoms and the tuberculous process is closer. Against a mere accidental concurrence speaks the considerable frequency of this combination. The theory that tonsillitis only causes the manifestation of the tuberculosis is contraindicated by the observation that not severe forms of tonsillitis precede the tuberculosis but usually comparatively mild forms, in which difficulty in swallowing is the main symptom, and there is a noticeable discrepancy between the slight local symptoms and the severe general symptoms, particularly the fever. In many instances this stage of the disease is not seen by the physician, but the anamnesis often reveals that an "influenza with sore throat" preceded the tuberculosis. The author gives several case reports and in the conclusion he admits that the relationship between tonsillitis and tuberculosis also has a reverse aspect; that a chronic tonsillitis, by its increased temperatures, may simulate tuberculosis. But the author thinks that because this is generally known to physicians there may be danger that a tuberculosis is overlooked. He therefore emphasizes once more that it should also be kept in mind that a tonsillitis may mask a tuberculosis.

*Painful Contralateral Reflex in Some Cases of Renal Infections. M. Cilento.—p. 667.
*Solieri's Plastic Method of Surgical Treatment of Hemorrhoids. P. Emiliani.—p. 670.
Pathology of Peripheral Nerves. Alteri.—p. 676.

Painful Contralateral Reflex in Renal Infection.—Cilento distinguishes four types of contralateral pain: (1) simple, spontaneous contralateral pain in the region of the normal kidney (on bimanual palpation of the renal regions the pain is produced only in the seat of the pathologic kidney and by the palpation of the corresponding region); (2) nonspontaneous contralateral pain caused by the pathologic kidney in which on palpation the pain is referred to the region of the normal kidney; (3) nonspontaneous contralateral pain caused by palpation of the normal kidney, and (4) nonspontaneous contralateral pain from palpation of the normal kidney associated with a muscular resistance of the abdominal wall on the side corresponding to the normal kidney. The functional reflex is more serious and important than the painful reflex and can even lead to a reflex anuria which only the extirpation of the pathologic kidney can overcome. In the renorenal reflexes the contralateral pain, observed in rare cases of unilateral renal ptosis without parenchymal alteration and elaboration of toxins, impairs the theory of toxins or secondary lesions in the opposite kidney. The author states that in two cases the distention of the pelvis of the pathologic kidney caused contralateral pain in the normal kidney. He stresses the importance of this symptom in cases in which the renorenal reflex is doubtful and investigation may elicit a reflex pain in the normal kidney, originating from the pathologic kidney.

Solieri's Method of Surgical Treatment of Hemorrhoids.—Emiliani criticizes six different methods of treatment of hemorrhoids, exposing their defects, and then describes the method of Solieri, which has been applied for many years with success and without stenosis or prolapse of the mucosa. It consists of an excision on the contour of the divulsed anus of three or four diamond-shaped areas, of which the internal triangle includes the hemorrhoidal mass of the mucosa and the external triangle includes the external hemorrhoids. When the cure is completed, the anal region is perfectly regular and smooth, intersected by three or four radiating linear scars.

Protection of Voice at Age of Puberty. L. Labarraque.—p. 672.
Anesthesia in Otorhinolaryngology. R. Moreno.—p. 680.

Left Dorsolateral Position in Appendectomy.—Leza states that appendectomy can be performed with good results, even in grave cases, by placing the patient in the left dorsolateral position for the operation. The patient (with the arms raised over the head), lies in the left dorsolateral position inclined at an angle of about 45 degrees, with a bag of sand or a pillow in the angle formed by the table and his back, in order to maintain the same position all through the operation. Under the influence of the patient's position the mobile viscera are displaced toward the left (the opposite side to that on which the operation is going to be performed). The cecum, being a semimobile organ, is displaced to the left only to a slight degree. It is preferable to localize the cecum by percussion and to make the incision (a small opening) along a line corresponding to its internal border, near its fundus, that is, at a distance of about 1 inch (2.5 cm.) from the spina iliaca toward the appendicular region. The cecum can be identified by applying a separator of Farabeuf to either of the borders of the small incision. The appendix can be exteriorized and removed by this technic in a few seconds; thus one avoids any unnecessary manipulation (except in cases of adherent retrocecal appendix or when there are some other complications). With this simple technic, appendectomy can be done under local anesthesia.

Pregnancy of Five Months: Left Bifid and Right Angulated Ureters. S. E. Bermann.—p. 1489.

Ovarian Grafts.—Castaño and Risolía obtained satisfactory results from ovarian autografts in forty-four oophorectomized women (under 40) and from ovarian homografts in seven other oophorectomized women (whose age ranged between 20 and 30 years, only one woman of this group being as old as 42). Young and healthy women who were going to have an operation for some condition, such as fibroma or appendicitis, were chosen as donors in cases of homografts. The receiver and the donor of the graft were operated on simultaneously in the same room by different surgeons so that the graft (a piece of the cortical part of the donor's ovary) could be implanted immediately after it had been removed, since when the graft is placed in Ringer's solution or other fluid or serum, or is not implanted immediately after having been removed, its vitality diminishes. It is advisable to perform the operation under local anesthesia of the superficial cutaneous layers, because the infiltration of anesthesia into the deeper layers of the operative field may cause a diminution of the vitality of the graft. The operation is well tolerated with local anesthesia. However, when dealing with emaciated or nervous patients, one may resort to general anesthesia. The following technic is used for the implantation of the graft: A paramesial incision (either right or left) 4 or 5 cm. long is made in the bi-iliac line, followed by an incision of the anterior sheath of the rectus abdominis muscle, in the same direction. The rectus abdominis muscle is slightly displaced and the graft is applied behind it. The sutures are inserted first on the sheaths of the muscle and then on the layers of the skin; care should be taken not to pinch the graft. Two or three days of rest are sufficient for the patient. The authors conclude that ovarian grafts may be resorted to in the treatment of the grave symptoms of ovarian insufficiency caused by the surgical removal of either one or both ovaries in women under 40 who do not improve under the action of uniglandular or pluriglandular opotherapy. The administration of series of daily injections of a solution made up with macerated human ovary from normal women is advisable to stimulate the action of the homograft. Ovarian grafts do not exclude the use of opotherapy. The action of ovarian grafts is not related to suggestion, as some authors have previously stated. If one takes in consideration the short time of activity of the grafts (about three years), the simplicity of the method and the easy technic of the operation, there seem to be no contraindications to implant a new graft when the activity of the graft previously implanted has ceased Further studies on this subject are advisable.

Route for Artificial Serotherapy in Obstetric Hemorrhages.—León made a detailed study on the intimate nervous relationship that exists between the mammary glands and the genital organs, and also on the influence that the intramammary injections of physiologic solution of sodium chloride have on the contractility of the uterus during pregnancy, physiologic labor and the puerperium. The author concludes that the intramammary administration of injections of physiologic solution of sodium chloride constitutes the treatment of choice to check genital hemorrhages of obstetric origin in those cases in which the elicitation of the mammary-uterine reflex may be of therapeutic use by provoking or increasing energetic contractions of the uterus. The treatment aims, at the same time, to improve the general condition of anemia caused by the hemorrhage and to secure hemostasis. The administration of injections of physiologic solution of sodium chloride by the intramammary route is contraindicated when the appearance or exaggeration of the contractions of the uterus may be considered as an unfavorable complication of the condition in the given obstetric case.

*Bilateral Facial Paralysis in Parotitis that Concurs with Symptoms of Infectious Polyradiculoneuritis. L. J. Nemlicher, W. W. Tschernikow and S. J. Solomonowa.—p. 292.

Neuritis in Pigmentary Cirrhosis.—Mancke observed five patients in whom the reflexes of the lower extremities, namely, the patellar and the achilles tendon reflexes, were absent. One case was clinically diagnosed as pigmentary cirrhoses; in three instances there existed pigmentary cirrhosis and diabetes, and the other patient had cirrhosis of the liver and diabetes. On the basis of the anamnesis and observation, an infectious as well as an exogenic toxic cause could be excluded. The examination of the central nervous system revealed in all instances only the disturbance in the reflexes. Motor and sensory disturbances as well as ataxia were not detectable. The author assumes that the abolition of the reflexes was caused by an endogenous toxic neuritis of the femoral or sciatic nerve, which is much more frequent during the combination of hepatic and pancreatic disorders than it is if either of the organs is affected alone.

Bilateral Facial Paralysis in Parotitis.—Nemlicher and his associates describe three cases of an infectious disorder, which had a subacute course and was accompanied by polyradiculoneuritic symptoms. The main symptom was a facial diplegia. On the basis of simultaneously existing slight inflammatory manifestations of the parotid gland, the disease was considered an abortive form of epidemic parotitis. For one of the patients, a boy, in whom the testes were involved, this theory is confirmed. As further proof the authors cite reports from the literature on the concurrence of polyneuritis with epidemic parotitis. The facial paralysis is considered to be directly connected with the glandular disorder. It is probable that from the primary diseased parotid gland the disorder spread to the facial nerve. Although in true mumps facial paralysis is relatively rare, the occasional concurrence nevertheless indicates in some cases a special affinity of the disease virus for the facial nerve. It is also pointed out that in some cases of facial paralysis a simultaneously existing disorder of the parotid gland may be overlooked. In the observed cases the general character of the disorder, among other signs the blood picture, seems to corroborate the assumption that epidemic parotitis is caused by a filtrable virus with neurotropic characteristics.

Lipoid Complex of Blood.—Fahrig and Wacker compared the lipoid complex of healthy persons during rest with that of patients with hypertension, during starvation, during pregnancy, following physical exertion and following ingestion of a meal with high fat content. Under lipoid complex they understand the phosphatides (computed as lecithin), cholesterol fatty acid esters, neutral fat and free cholesterol. They found that during essential hypertension there usually exists a hyperlipoidemia. Thus the hypercholesteremia that is often discussed in the literature is only a partial manifestation of the hyperlipoidemia. The other constituents of the lipoid complex are likewise increased, so that the physiologic ratio is largely preserved. The hyperlipoidemia that develops during hunger, pregnancy and following physical exertion shows, in regard to the composition of the lipoid complex, great similarity to the hyperlipoidemia during essential hypertension. In contrast to these forms of hyperlipoidemia, the digestion lipemia that develops after eating a meal with high fat content is characterized principally by a great increase in neutral fat. It is mainly due to fat resorption, whereas the other forms of hyperlipoidemia are primarily an indication of a changed intermediate fat metabolism. During starvation, during pregnancy and following bodily exertion, hyperlipoidemia is probably due to an increased mobilization and utilization of the lipoids for energy production. Exhaustion of the carbohydrate reserve during starvation and increased energy requirements during physical exertion and during pregnancy make an increased fat exchange understandable. The increase in the basal metabolism during constantly increased resistance in the peripheral vessels, and the use of lipoid substances by the cardiac muscle, indicate that the hyperlipoidemia during essential hypertension can likewise be explained on the basis of a greater need for energy producing lipoids. The significance of the increased cholesterol content, aside from its function as a transport form for fatty acids, remains unexplained. The acidoses that occur during hyperlipoidemia are produced either as in starvation and perhaps also in pregnancy by intermediate products of the fat metabolism (ketonic acid, beta-oxybutyric acid) that occur in carbohydrate deficiency, or, as in physical exertion, by lactic acid, a decomposition product of the carbohydrate metabolism. The increased lactic acid content that the authors observed in one case of essential hypertension may also be a result of the constantly increased cardiac action.

Carbohydrate Metabolism in Patients with Diphtheria.—During the acute stage of diphtheria, Brems observed quite frequently a moderate increase in the sugar content of the blood. During the acute stage of cases of medium severity and in severe cases, the blood sugar curve following an oral dextrose tolerance test was frequently abnormal. With its extremely high maximal values and the considerably prolonged hyperglycemia, it resembled strongly the conditions in diabetes mellitus. This abnormality of the alimentary blood sugar curve is not caused by fever but by a toxic disturbance in the regulation of the blood sugar, which may be due to functional disturbances in the suprarenals, liver and pancreas. From one to two weeks following the first dextrose tolerance test, the curve became nearly or entirely normal. Spontaneous glycosuria was occasionally observed during the acute stage of a severe diphtheria; after dextrose tolerance tests it was nearly always demonstrable.

Hypertension in Young Persons.—Walko examined 1,700 male and 120 female students between 16 and 22 years of age for the presence of hypertension. Among the male students he detected hypertension in 17.4 per cent and among the female students in 8.3 per cent. In the majority of cases the hypertension was of the labile type, and the persons affected with it were of the nervous, constitutionally weak, irritable and vasolabile type. Only in a small number was the hypertension of the fixed type. Because a large percentage of the students who had hypertension were consumers of large quantities of alcohol or of tobacco, some being users of both, the author thinks that the constitutional, particularly the nervous, factors are not the only causes of the early manifestation of hypertension, but that alcohol and nicotine are also responsible. In addition to this, many of the young people who had hypertension took little or no exercise. In discussing the treatment of hypertension the author states that systematic exercise, without any attempt of record accomplishments, was beneficial and led to a reduction in the blood pressure. Regulation of the mode of life, a proper diet and the restriction of the use of alcohol and of tobacco were also found helpful. Because the vascular reactions were largely psychogenic and because of disturbances in the sympathetic nervous system, psychotherapy was used.

High Carbohydrate Diet and Diabetes Mellitus.—Induced by Porges' studies, by which it had been revealed that the carbohydrate tolerance of diabetic patients can be increased by a diet deficient in fat but comparatively rich in carbohydrates, Czoniczer and Kolta tried to duplicate these results; but they wanted also to determine to what factor the efficacy of this diet can be ascribed. They doubt Porges' assertion that the increased tolerance is primarily due to the fat deficiency of the diet. Their first observations convinced them that the increased tolerance is mainly due to the low number of calories and the comparatively high carbohydrate intake. After that they tried to determine how the tolerance of the diabetic patients is influenced by the excessive carbohydrate intake. The solution of this problem seemed important, because it is generally believed that the carbohydrate intake which exceeds the limits of tolerance exacerbates the patient's condition. The authors made their observations on fifteen patients in whom the diabetes was either slight or of medium severity. In severe cases, in which there exists complete pancreatic insufficiency, a favorable influence of an excessive carbohydrate content was not to be expected, and since one experiment in this direction corroborated this assumption, other severe cases were excluded from the further tests. In the mild and medium severe cases it was noted that, in the first few days of excessive carbohydrate intake, the sugar elimination increased. The maximum was usually reached after two or three days, and then it decreased gradually to the level at which it was before excessive amounts were given. The increase in tolerance varied between 20 and 80 Gm. of carbohydrates. On the basis of these observations, the authors conclude that the ingestion of carbohydrate not only consumes insulin but also has a stimulating effect on its secretion.

Studies on Acid-Base Economy in Children.—Forschner-Böke and the Hottingers studied the acid-base economy in children following oral administration of acid and basic substances. 1. They found that after oral administration of sodium bicarbonate the elimination of organic acids is considerably increased. However, this increase is not due to an increased elimination of ether soluble fatty acids. The elimination of amino-acids is strongly and that of uric acid and of creatine is slightly increased. Between the elimination of amino-acids and of ammonia there seems to exist an interrelation. It is particularly phosphoric acid that is used for maintaining the acid-base equilibrium. The ammonia content of the urine is usually decreased. 2. When large quantities of mineral acids are fed to nurslings, the general metabolism is only secondarily affected. The neutralization takes place primarily in the intestine, and during this process water and bases are withdrawn from the organism. 3. Oral administration of oxyisobutyric acid increases considerably the elimination of organic acids in the urine. The quantity of the ether soluble fatty acids, as well as of the amino-acids, is increased. The elimination of organic acids exceeds the intake of organic acids considerably. 4. During prolonged feeding with lactic acid the organism decomposes the administered organic acid to such an extent that an increased elimination of lactic acid cannot be observed. When lactic acid is given for only a short period to older children, the following results are obtained: The elimination of organic acids is considerably increased. The lactic acid content of the urine indicates that the increased elimination of organic acids is only partially due to unchanged excreted lactic acid. The increased elimination of amino-acids likewise indicates that the greater excretion of organic acids is the result of changes in the intermediate metabolism.

Thrombopenic Purpura Following Smallpox Vaccination.—Dormann relates the clinical history of a child, aged 7 months, who from the sixth to the seventh day following smallpox vaccination developed signs of a purpura. Clinically it was characterized by hemorrhages from the skin and from the mucous membranes and hematologically by thrombopenia. The manifestations disappeared within three days without a therapeutic intervention. The author further reviews two similar cases from the literature and she thinks that a connection between the thrombopenic purpura and the smallpox vaccination can hardly be doubted. However, it cannot be definitely decided whether the vaccination caused the purpura or only led to its manifestation. The rarity of its development in the large number of vaccinations seems to indicate that an endogenous factor is involved. Whether this factor will manifest itself only in a single attack or whether later an essential thrombopenia will develop can be determined only by further observation of such patients.

Toxin and Antitoxin Content of Spinal Fluid in Postdiphtheritic Paralysis.—Quest points out that diphtheria toxin has a special affinity for the nervous substance and he thinks that the postdiphtheritic paralysis which develops between the second and sixth week of the disease is a manifestation of this affinity. The paralysis (really more of a paresis) involves primarily the soft palate, the muscles of the eye and the muscles of the lower extremity; more rarely there is paralysis also of the facialis, of the muscles of pharynx and larynx, and only in exceptional cases the respiratory muscles, particularly those of the diaphragm are involved. A review of the literature on the changes in the spinal fluid during diphtheria revealed that diphtheria toxin and antitoxin have never been detected. The author thinks that the absence of the toxin might be due to the fact that it is bound to the nerve cells; however, the absence of antitoxin was the more surprising, since antitoxin was always found in the blood. He then relates the results of his own studies on nine children with severe manifestations of postdiphtheritic paralysis. Tests for the presence of toxin and antitoxin in the spinal fluid always gave negative results.

Ovary and Endometrium in Patients with Myoma.—Häggström's investigations were made on the ovaries and the endometrium of fifty-six patients with myoma. In regard to the size of the ovaries he states that in twenty-eight, that is, in exactly 50 per cent of his patients, the ovaries were of normal size. In eleven of the remaining twenty-eight, one ovary was of normal size. In seventeen cases, both ovaries were larger than normal. In general the size of the myoma exerts only a slight influence on the size of the ovaries, for normal as well as enlarged ovaries are found during existence of small and of large myomas. The consistency and the position of the myoma has no influence on the weight of the ovaries. In counting the follicles it was found that in younger women they were more numerous than in older women. The corpora lutea of the patients with myoma did not differ from those in normal ovaries, and thus the author cannot corroborate the opinion expressed by some investigators that they are especially large. Corpora albicantia were found in all instances and in the majority of cases they were numerous. The latter fact, which by some is considered as a characteristic of the ovaries of myoma patients, the author considers a natural result of the advanced age of these patients. Ovarian hemorrhages were present in thirty-six of the fifty-six patients and were found most frequently in myomas of medium size. Cystic degeneration was noted in nearly half of the ovaries. In thirty patients the ovaries showed signs of an existing or of a former inflammation. These signs of inflammation were more frequent in cases of larger than in smaller myomas. In seven instances small fibromas were found on the surface of the ovaries, but these fibromas do not seem to have an influence on the hemorrhages in the myomas. Observations on the hyalinization of the ovarian vessels convinced the author that the degree of hyalinization is more closely connected with the age of the woman, with the number of confinements or with both of these factors than with the myomas. The endometrium was examined in fifty-four of the fifty-six patients. In twenty-three instances it was entirely normal. In twenty-one cases the mucous membrane was atrophied, and hypertrophy was noted in only four instances. A change, characteristic for myoma, could not be detected in the uterine mucosa. Observations on fifteen sterile women of the author's material indicate that, as the size of the myoma increases, the greater is the likelihood of sterility. The position of the myoma appears to exert no influence on the sterility.

*Metabolic Action of Inhalation of Pure Oxygen. P. Bielschowsky and S. Thaddea.—p. 330.
*Arsphenamine and Bilirubin Content of Blood. O. Satke and K. Thums.—p. 386.

Metabolic Action of Inhalation of Pure Oxygen.—Bielschowsky and Thaddea examined first the influence of inhalation of oxygen on the ketone bodies in the blood and on the acid-base equilibrium. They found that it effects a decrease in the ketone body content of the blood of patients with increased ketone body content. It also increases the alkali reserve and causes changes in the hydrogen ion concentration toward the alkaline side, particularly by a decrease in the alveolar carbon dioxide tension. The authors also examined the influence of oxygen inhalation on the lactic acid content of the blood following intravenous tolerance tests with a 20 per cent solution of sodium lactate. These tests were made first on dogs and then on human subjects, and it was found that when the tolerance test was combined with oxygen inhalation the curve indicating the lactic acid content was considerably lower than when only air was breathed. In order to determine the influence of oxygen inhalation on the lactic acid content without the tolerance test, epinephrine was administered, which ordinarily produces a considerable increase in the lactic acid content in the blood. It was again found that when oxygen was inhaled the lactic acid curve was considerably lower than when only air was breathed. The authors then discuss the action mechanism of the oxygen inhalation but reach no definite conclusions.

Arsphenamine and Bilirubin Content of Blood.—Satke and Thums direct attention to the fact that liver disturbances, particularly icterus, frequently develop following antisyphilitic treatment with arsphenamine. Because the opinions are still divided as to whether the disturbance of the liver is due to syphilis or to the treatment, the authors studied the modification of the bilirubin content produced by administration of arsphenamine. After mentioning a number of investigators who have studied this problem from various angles, the authors describe their own tests. They noted that arsphenamine influences the bilirubin content of the serum in more than 50 per cent of the cases. In one fourth of these abnormally reacting cases the bilirubin content is increased, whereas in the other three fourths of the cases it is decreased. This behavior was seen in cases with an originally normal bilirubin content as well as in cases with a bilirubin content that was increased before administration of the arsphenamine. In order to determine whether the arsphenamine effect was influenced by the size of the dose or by a disturbance in the liver function, the arsphenamine was given in smaller and in larger doses (but never in excess of 0.45 Gm. of neoarsphenamine), and the liver function was tested by the galactose test. However, neither of these two factors were found to be of influence.

Prophylactic and Therapeutic Significance of Calcium in Obstetrics and Gynecology. J. Malfatti.—p. 1358.

Treatment of Genital Hemorrhages with Corpus Luteum Hormone.—The physiologic function of the corpus luteum consists, according to Kaufmann and Bickel, in the protection of the ovum and of its site of attachment, the mucous membrane, which it prevents from disintegration and from subsequent hemorrhage. The fact that the corpus luteum hormone inhibits hemorrhage seems to justify its use in the treatment of gynecologic hemorrhages. Accordingly, the authors employed it in sixteen cases of severe uterine hemorrhages. In the majority of these cases, other therapeutic methods had been used without avail. In twelve of the patients the hemostatic effect became noticeable from seven to eight hours after the first injection, but hemorrhage generally recurred from twelve to sixteen hours later and did not disappear again until several additional injections had been given. However, more important than the immediate effect the authors consider the regulating influence on the menstruation. In three of seven women the cycle became almost normal, whereas in three the intervals as well as the duration remained irregular. In the other patient it was regular with only one menstruation of prolonged duration. Three women who were in the premenopausal age, and who had hyperplasia of the uterine mucous membrane, were observed for several months following the corpus luteum therapy, and in these cases clinical cure was effected. The treatment proved likewise helpful in a girl, aged 17, who for a year had almost continuous hemorrhages with rare intermissions. In this case other therapeutic measures had been employed without avail, but after corpus luteum treatment the cycles became regular. Four women discontinued the treatment early, before results were obtained, but in spite of the comparatively small number of cases the authors feel justified in calling attention to the possibilities of treatment with corpus luteum hormone.

Problems of Medicolegal Expert. N. V. Popov.—p. 424.
Public Health in Stalingrad Tractor Plant. I. L. Glezer.—p. 441.

Atropine in Treatment of Pulmonary Hemorrhage.—Trofimov gave subcutaneous injections of 1 mg. (ten instances) and 0.5 mg. (one instance) of atropine sulphate and found that atropine increases the circulation of the peripheral system and causes a rise in the skin temperature; there is an increase in the circulation of blood in the greater circulation concomitant with a decrease in the lesser circulation. These observations prompted him to use atropine in the treatment of pulmonary hemorrhage and hemoptysis. In six of ten patients, from one to three injections were sufficient to stop the hemorrhage; in two patients, complete cessation of the hemorrhage was possible only after prolonged treatment; and in two other patients the treatment was without effect. Atropine was effective in doses of 0.5 mg. or less; when the pulmonary hemorrhage was profuse, treatment was begun with doses of 1 mg., followed after three hours with 0.5 mg. and after five hours, again, with 0.5 mg.; when the hemoptysis was moderate, the dosage was 0.5 or 1 mg. twice a day. Atropine is contraindicated in gastro-intestinal hemorrhage. The best results are obtained in hemorrhage during a freshly induced artificial pneumothorax. Atropine is indicated in hemorrhage from an aneurysm and previous to the induction of an artificial pneumothorax. The action of atropine is greatest in vagotonia and least in sympathicotonia.

Atmospheric Influences (Noso-Aerial Factors) and Incidence of Scarlet Fever. H. von Willebrand.—p. 337.
*So-Called Spontaneous Panophthalmia. O. Heinonen.—p. 360.

So-Called Spontaneous Panophthalmia.—Heinonen reports that in a woman, aged 30, with a severe cold, a comparatively slight, transient pneumococcus infection occurred; at the same time menstruation set in. On the second day, when the fever was receding, a metastatic retinitis appeared and in a few days panophthalmia developed. Evisceration of the eye was followed by uneventful recovery. Microscopic examination of the exudate showed pneumococci in pure culture. The author thinks the portal of entrance for the pneumococcic infection in the blood was the upper respiratory passages, with the premenstrual constriction of the capillaries probably a disposing factor for the appearance of the infectious embolus in the retina.

*Pancreatitis as Complication in Epidemic Mumps. E. Sylvest.—p. 508.
*Acute Infectious Disease of Central Nervous System: Cases. H. Schmedes.—p. 514.

Pancreatitis as Complication in Epidemic Mumps.—Sylvest says that pancreatitis may occur directly after the onset of the mumps or later in the course of the disease and is manifested by fever, nausea, vomiting, disturbance in intestinal function, pain and tenderness in the cardia; there is occasionally a palpable tumor with location corresponding to the seat of the pancreas, and the fasting blood sugar values are usually increased. As a rule the disorder is of brief duration, but it may extend over several weeks.

Acute Infectious Disease of Central Nervous System. Schmedes reports seven cases, observed during January in one family, of an acute febrile condition of the central nervous system, partly of definitely infectious character. The cases were polymorphic in kind but were diagnosed as acute anterior poliomyelitis. Poliomyelitis, the author says, rarely occurs in the district in question, and there were no other cases in the immediate vicinity; careful investigation failed to reveal the source of infection. Four additional cases are reported which were also seen in the same month, at a considerable distance from the other cases.

THE CRIPPLED CHILD VERSUS THE CHRONIC SICK OF MASSACHUSETTS

CHAIRMAN'S ADDRESS

JAMES WARREN SEVER, M.D.
BOSTON

My original intention was to confine my observations to the problems of the care and education of the crippled child of Massachusetts.

As an exhaustive survey of this subject has not only been recently completed but presented in a remarkably clear report by the Massachusetts Department of Public Welfare, a report that could not fail to interest the medical profession and the general public as well, I will forego unnecessary repetition. I therefore desire to focus attention, first, on education and usefulness of the cripple, and, secondly, on the problem of the chronic sick.

After working for more than twenty-five years in orthopedic surgery, I am hopeful and optimistic for the constantly increasing interest in crippled children, their physical care, education and economic usefulness and the desire and interest on the part of society to give them a square deal with every opportunity for happiness.

The crippled child starts life with a great handicap, but also with an equal appeal to the love, pity and intelligent interest, not only of his parents but of the public at large and of the state in particular. The state is interested from two important angles: first, the economic usefulness of the child to himself and others, and, second, the purely humanitarian desire to alleviate suffering and correct deformities.

For the purpose of clarity I quote the definition of a crippled child adopted by the Massachusetts survey: "A Crippled Child is one who does not have the normal use of bones and muscle for education and work."

This state report shows conclusively that the interest and benevolent attention to this group of society has been steadily on the increase since 1895, when a privately conducted day school in Boston was established to "promote the education and special training of Crippled and Deformed Children" (The Industrial School for Crippled and Deformed Children). Almost simultaneously, the New England Peabody Home for Crippled Children was established. Ten years later, the Massachusetts legislature recognized the importance of providing special care and education for the crippled and deformed children of the state by the establishment of the Massachusetts State Hospital School at Canton. Since then hospital facilities, home care and rational discriminating cooperation between parents, physicians, orthopedic surgeons and school and district nurses have been steadily on the increase, with a corresponding intelligent understanding and provision for the educational and occupational training of crippled children now and in the future.

Massachusetts has twenty-one hospital schools, eighteen when one eliminates for obvious reasons the three large schools for the feebleminded, which not only care for the physical deformities but also give training in regular school courses to the patients, courses suited to their mental capacity and development, together with manual, occupational and sense training. This class of child is in no way included in this study. It seems to me a field quite apart from the group ordinarily catalogued as crippled children.

As a result of the Massachusetts survey, data concerning the entire 6,141 crippled children were obtained; first, as to the causes of crippling conditions, second, classification according to the amount and permanence of the handicap; third, classification according to noncrippling defects, and, fourth, classification according to economic prospects.

Data were also procured concerning 1,034 crippled children listed as institutional patients, known as group A. These data included: (1) their distribution in institutions, (2) classification according to age, disability and sex and (3) institutions in Massachusetts caring for crippled children of this group.

Comprehensive data on the following points were obtained concerning the 5,107 crippled children who are catalogued as noninstitutional patients, or belonging in group B: (1) whether the children were living at home or temporarily being cared for in hospitals maintaining active surgical units, (2) geographic distribution, (3) classification according to age, disability and sex, (4) treatment and (5) education.

Admitting that happiness is as indispensable and desirable for the cripple as for the normal person, it is essential that the economic future of the child be considered. All treatment should point toward reducing the handicap and, at the same time, should train the crippled child to the proper mental attitude toward his disability, which will enable him to compete with normal persons. This adjustment should begin early in life, through the combined efforts of the physician, the parents and the schools.

When the cripple has received the care and training necessary for him to take his place in the world as a self-respecting, independent and self-supporting citizen, his next need is the proper opportunity for such self-support. I refrain from quoting figures and tables and giving specific cases, all of which are far better understood and retained when read. They are clearly set

---

Read before the Section on Orthopedic Surgery at the Eighty-Third Annual Session of the American Medical Association, New Orleans, May 12, 1932.

forth in the report just published by the Massachusetts Department of Public Welfare relative to the "Number and Care of Crippled Children in Massachusetts," which furnishes comprehensive and instructive reading for those interested in the crippled child, who is "one who does not have the normal use of bones and muscles for education and work."

Keeping this in mind, there is one comparison of figures I should like to state briefly, to make more emphatic the points I am laying the most stress on, namely, education and usefulness through opportunity.

Comparison of the education of group B, noninstitutional patients (the largest group) with the education of all minors in Massachusetts (figures estimated from the 1929 school census and the 1930 federal census) shows that the educational status of children of group B compares favorably with that of other children.

The 1,563,127 persons under 21 years of age in Massachusetts are classified in age groups as follows: 497,622 under 7 years of age, 553,009 between 7 and 14 and 512,496 between 14 and 21.

Of the 497,622 normal children under 7 years, 26.58 per cent are receiving education and 73.42 per cent are not. Comparison with the figures for the 919 crippled children of the same age group shows a difference of 0.84 per cent in favor of the crippled child.

Of the 553,009 normal children between 7 and 14 years of age, 99.76 per cent are receiving education and 0.24 per cent are not. Comparison with the figures for 2,298 crippled children of the same age group shows a difference of 11.20 per cent in favor of the able-bodied children. This difference may be somewhat accounted for by the fact that the crippled group includes a large number of children out of school for treatment, others who are mentally unpromising as well as crippled, and also many now receiving education under the provision of the new law requiring home teaching for crippled children.

Of the 512,496 normal children between 14 and 21 years of age, 33.50 per cent are receiving education and 66.5 per cent are not; compared with the figures for 1,890 crippled children of the same age group, there is a difference of 35.65 per cent in favor of the crippled child. This difference, however, may be accounted for somewhat by the fact that the education of the cripple is often continued at an age when the able-bodied child has left school for work.

Except in a comparatively few instances, the educational problem has been met pretty squarely by the parent and child. However, there is still room for enlightened cooperation and discriminating understanding to remove doubt and prejudice, but this will undoubtedly be counteracted by the increased facilities for handling these children in the public schools and in private and special schools conducted for them, and also through the law recently enacted which provides that in every town or city where there are five crippled children who cannot attend school a teacher shall be supplied by the local school department to teach them in their homes. The result is that over thirty cities and towns give home instruction to crippled children.

Also, the services of the Rehabilitation Section of the Department of Education are available for any resident of Massachusetts of legal age for employment whose physical disability is a vocational handicap and who might reasonably expect to be fitted for remunerative employment.

The Massachusetts enactment provided for a continuing survey and supervision of the Department of Education and Public Welfare. It should make possible a broader social service for crippled children all over the state.

The service is and will be directed further toward finding the crippled, educating the parents in the necessity of suitable treatment and education for their children, insuring continuity of treatment by follow-up work and educating the public to the proper attitude toward the cripple, so that those who are able may be given the opportunity to earn their own living.

To quote the survey:

> The general public of Massachusetts has generously responded to the appeal for funds to aid the Crippled Child. It has helped to bring treatment and happiness and insisted upon every possible educational advantage.
>
> But is it now ready to give employment? When the Cripple comes seeking work does it look beyond the physical handicap to the personality? Does it realize that he is not seeking sympathy, in fact does not want it, that he has been trained and has learned by necessity the art of doing things well in spite of his handicap, that what he wants is an opportunity to prove that he can fill well the position which he seeks?

I believe that hospitals that minister to the needs of children stimulate the most urgent appeal and obtain the quickest response from a wide and generous public.

Is there a similar claim and discerning intelligent interest in the physical care and the mental adjustment of the chronically sick? What can the state do for this unfortunate group of citizens? Will private philanthropy again blaze the trail for the chronically sick as it did for the crippled child?

Will people of great wealth be willing to consider seriously and desire to endow a much needed and deserving form of charity so seldom ministered to or adequately provided for by philanthropists?

One contemplates the ever-increasing duplication of memorial libraries, monuments, chapels, windows, organs and chancels, elaborate dining and lounging halls, expensive recreational facilities donated to private schools and universities, and towers raised on every conceivable structure. As many of these bequests have been given in the memory of fathers, mothers, husbands, wives and children, one asks why people still possessing and amassing huge fortunes do not more often feel the urge and interest to give generously to a neglected group of society, the adult chronically sick of the great middle class with small incomes, men and women who, through no fault of their own or lack of industry, may become what is known as the "chronic sick"?

Despite the fact that in our states, almost every city has its general and private hospitals, and that towns, alone or in groups, maintain and support well equipped hospitals for the care of the acutely sick, hospitals that are generous and helpful for periods as long as their boards or endowments permit, sooner or later arises the question, so difficult to meet satisfactorily: "What is to become of patients discharged, who from necessity must be catalogued as 'chronic sick'?" For instance, take the large group of unfortunates who would come under the group of arthritic patients, with all that this condition involves.

Fortunately, one does not need to consider so carefully the two extremes of humanity, the rich who can afford to have all possible comforts and attention and opportunities for happiness, and the very poor who by circumstances of birth, lack of education and opportunity are generally provided for in state, county or city infirmaries or almshouses.

The medical profession at large would surely admit that these two extremes of society are far better provided for than the intermediate class, by reason of the tendency to erect expensive private wards and the philanthropic desire to maintain charitable or semi-free beds for people able to pay little or nothing. Four persons confessed that in recent long illnesses in their families the patients were cared for at home just as soon as they could safely be discharged from the hospital, in spite of the conviction that they should have remained longer. This was due to the fact that there was insufficient accommodation in the lower priced private rooms, and that the patients and their families were so distressed over the cost of the luxurious rooms, together with necessary nursing and other bills, that the situation was not conducive to a happy recovery. The feeling was unanimous that there was an immediate need and demand for more plain, simply furnished rooms, at, say, $6 a day, which would add to the peace of mind of the patients and those responsible for them; instead they were being cared for on a scale that they could ill afford and did not desire. It would be interesting to know whether this rational state of mind has been one of the chastening results of financial depression or whether it is due only to the wisdom of mature years, which teaches most of us the uselessness of nonessentials in important matters. The latter would not seem to be the prime factor, for I consulted a number of physicians, in varying fields of medicine, who insisted that the majority of their young married patients were more than ready to reject and eliminate nonessentials.

In cases of the chronic sick it is difficult to find suitable care and homes for people of slender means. Such private institutions as exist are generally crowded, with long waiting lists, or are conducted in such a manner as to be too expensive for the average income of the big middle class.

There would seem to be an urgent need for the endowment of institutions where people of refinement and education with chronic conditions can go after being discharged from the hospital and where, by the payment of reasonable sums of money, they can feel not only secure but self-respecting, and not be a burden to families unable to care and provide properly for a chronically sick person in their midst. This is especially important, since so many people who are in this group have led busy, industrious lives, earning their living in necessary, but frequently, underpaid professions.

What also seems worth considering is the question whether institutions for social betterment would be just as useful if they were run on less extravagant lines, so far as buildings, equipment and maintenance are concerned. This seems an important consideration in future requests for funds at a time when even well established and undoubtedly valuable charitable and private educational institutions are making constant appeals to the general public with not too successful or immediate results.

An executive of an important industry was recently asked why in his organization, a few years ago, with an increased output and business, they discharged certain people. He replied:

> Remember, we are not a charitable or educational institution, spending the invested funds or subsisting on the benefactions of a well solicited public. We cannot afford to keep in our employ people who do not prove that they can earn their salt or who are not essential additions to our company.

Of course one is aware of the indignant rejoinder of certain people who will immediately say that charitable and educational institutions cannot be run like a business. However, the truth remains that some successful ones can and do function satisfactorily without such lavish expenditures for nonessentials. There will be those who say that there is much wealth still untouched to endow further institutions. To whom and for what will they minister?

An ordinary inmate or observer would not presume to judge adequately of the value of the lavish expenditure displayed in schools and universities and the sumptuously equipped charitable institutions, and one does not desire to raise undue argument in regard to the relation of efficiency to the expenditure of public bequests. But one simply wonders why, if so much money is available, more people with large means do not feel encouraged to endow suitable and comfortable, not necessarily lavishly luxurious, hospitals and homes for the self-respecting chronically sick adult.

Any physician can furnish as deserving examples as the following: A librarian, finding herself crippled in late middle life, is now faced by the devastating fact that at present, cared for as she is obliged to be, in a private nursing institution, the expense is so great that unless she is fortunate enough to die in a few years, she will have exhausted her entire capital. A retired school teacher, living contentedly in a tiny apartment, doing her work and laundry and living simply as to food and pleasures, met with an accident which, after months of acute illness, left her in a condition in which she could neither take entire care of herself nor continue to stay where she was and have an attendant. This woman was not only capable of much mental happiness for herself, but she had the spirit and ability to be useful to others through her fine mental attainments, if she were where she could be of service. Her nearest relation, a niece, was married to a man whose profession entailed frequent changes of locality, if husband and wife wished to live together on a rather small salary. The patient neither felt herself entitled to nor did she desire to enter a city home, and she could not afford the cost of the average nursing home or sanatorium run as a business venture. The problem was to find suitable part time care and accommodations where she might be happy and not feel herself an object of charity.

A man crippled by arthritis and unable to work suddenly lost his devoted wife, who had been able not only to supplement their income by her own efforts, but had cared for him and their tiny home. They had two children living at a distance. A son, either from lack of sympathy or means, or a combination of both, refused to help solve this problem. A daughter, happily married to a public school teacher, not only was bringing up her little family—one child had recently had infantile paralysis—but for years had had her husband's mother living as a dependent in her home. The father neither desired to add to her burden nor to try to adjust himself to a situation that was difficult, to say the least.

These few examples are typical of many deserving American people suffering from conditions of health that would seem more bearable if the people could be more free from a financial strain, in congenial surroundings.

The average boarding house does not solicit guests of this type. There are a few well run institutions for "chronics" or "incurables," some of which have more alluring titles engraved on their stationery and displayed over their doors. All are overcrowded with long waiting lists and, by reason of their religious faith or endowments, are largely filled with the people for whom they were designed, who are generally able to pay little or nothing. The other alternative is the city home, town poor farm or state farm, with hospital facilities. None of these institutions would seem to fit or expect to minister to the physical and spiritual needs of persons such as those just mentioned.

These people do not ask or desire unadulterated charity; they need an opportunity for reasonable care and for a chance for friendly intercourse and companionship among their contemporaries and equals.

Endowments are suggested for more institutions so built and managed that these people of slender resources can afford to enter them, not entirely as objects of charity, but as self-respecting paying guests and patients, who are able and willing to be cared for on a scale commensurate with their income Who must make the appeal and blaze the trail for Massachusetts or other communities?

321 Dartmouth Street

NEUROLOGIC FEATURES OF PERNICIOUS ANEMIA

RICHARD H YOUNG, M D
NEW YORK

Studies of pernicious anemia have shown the presence of a wide variety of associated lesions in the central nervous system. As early as 1880, Little[1] described cephalalgia, vertigo, syncope, neuralgic pains and mental depression, along with other symptoms of pernicious anemia. The exhaustive work of Russel, Batten and Collier[2] followed that of Lichtheim,[3] Putnam[4] and Dana[5] in the early description of the spinal cord changes. Certain of the lesions described by the former authors have not received mention since. Barrett[6] and, particularly, Woltman[7] have called attention to the cerebral changes. Bastianelli,[8] Putnam and Taylor[9] and others have reported optic atrophy in association with pernicious anemia. The sensory changes have been described by many authors, but the work of Hamilton and Nixon[10] is an excellent review of the subject and, in addition, reports pathologic changes in the peripheral nerves. A recent article by Michaud[11] mentions bulbar symptoms.

The present paper deals with an analysis of the neurologic aspects in patients with pernicious anemia who have been admitted to the Peter Bent Brigham Hospital from its opening in 1913 to January, 1931. There is danger of burdening the literature when such excellent reviews by Woltman,[12] Smithburn and Zerfas[13] and others are available. However, the review of such a large number of cases, 515, while containing all the more common neurologic lesions in association with pernicious anemia, presents in addition a smaller group of lesions that have not received the attention they deserve. The observations so well epitomize the literature on the subject that they deserve mention, even if in brief form.

INCIDENCE

The incidence of changes in the central nervous system in pernicious anemia has been variously reported. McCrae[14] reported 25 per cent in a series of forty patients; McPhaedran[15] found 40.9 per cent in a series *of twenty-two patients, and Woltman*[12] *discovered* changes in 80.6 per cent of 150 patients. A recent report by Smithburn and Zerfas[13] describes paresthesias as being present in 95.6 per cent of 115 patients. The great variance in incidence would seem to be largely dependent on the accepted criteria.

Michaud,[11] in his paper, bases his figure of 40 per cent on the more advanced changes.

In this series of 515 cases there were 103, or 20 per cent, of the cases with well defined cord changes marked by reflex changes and ataxia. *The incidence would have* been much higher if lesser changes of the nervous system had been included.

The belief, as expressed by Michaud and others, that combined system disease is seen more frequently today is borne out in this group of cases. With the summer of 1925, when liver therapy was inaugurated at the Peter Bent Brigham Hospital, as an arbitrary date, the incidence has been 26 per cent as compared with 15.9 per cent before that time

AGE

The cord changes were found most frequently between the ages of 40 and 65. Since 1926, the majority were in the group between 50 and 65, while before that time the greatest frequency was in the 40-50 age group. Five per cent of the 103 patients were between 35 and 40 and 3 per cent in the 30-35 age group.

SEX

Combined sclerosis was found in about equal numbers in males and females. In the 103 cases of combined system disease, 48 per cent were males.

ONSET

The onset of the neurologic involvement in relation to the course of the disease pernicious anemia has been shown to be most variable. The neurologic symptoms may appear with the blood count at almost any level. A review of the admission blood counts in this series shows that most frequently the range was from 2 to 2½ million red cells. Occasionally the red count was near normal. This last condition seems to have been much more frequent since the institution of liver therapy. Changes of the nervous system developed in not a few cases with a red count of slightly over 4 million, a

majority of which cases were those in which there had been failure to take sufficient of a potent liver extract.

The most frequent inaugural neurologic symptom was paresthesia, which was also characterized by its very early appearance in the disease. Girdle pain, chiefly abdominal in location, may be present as an early symptom. Of the 103 cases with combined system disease, 13 per cent presented such girdle pains. At times the pain was associated with indigestion and simulated gastric crises. In this series, the girdle pain in recent years has been quite rare. Murphy[16] states that backache may be a presenting complaint. A small group of patients complained of what was termed a "neuritis," both brachial and sciatic in location. In a rare case mental changes developed as the earliest sign.

CLINICAL FEATURES

Cerebral Manifestations.—This phase of pernicious anemia was the subject of study by Woltman. In the 515 cases of pernicious anemia reviewed here, 4.5 per cent showed psychotic trends. The mental state seemed to vary considerably and included acute deliriums, depressions, paranoid states, and memory and disposition changes. It may be observed that the patient ill with pernicious anemia is quite frequently a cantankerous, refractory patient. However, once the remission starts, the change in disposition is often remarkable.

Among the cases presenting psychotic changes which came to autopsy, several interesting changes were observed. These included a chronic pachymeningitis and leptomeningitis and, in a second case showing symptoms of short duration, a thin subdural blood clot. There was, however, no complete pathologic study of any patient in this group with cerebral manifestations.

Ophthalmoscopic Examination.—A tabulation of the ophthalmoscopic observations in the cases of pernicious anemia with combined sclerosis showed that out of eighty-seven cases with careful ophthalmoscopic examination only ten yielded evidence of retinal hemorrhage. Eight of the ten were patients who suffered chiefly from psychotic manifestations. In this series, it was observed that the patients with pernicious anemia with a well marked psychosis almost invariably had retinal hemorrhages. There appeared to be no relationship between the presence of arteriosclerotic changes as portrayed in the fundi and the development of cord changes.

Optic atrophy in pernicious anemia, while rare, has been reported. In this series of pernicious anemia cases the condition was found to be present twice.

One of these patients, a man, aged 67, has been under observation for four years. In October, 1928, a year after his first admission to the hospital, for pernicious anemia, the patient experienced an exacerbation with increase in neurologic symptoms and a failing vision. The patient stated that he had averaged three-fourths pound (340 Gm.) of liver a day, but by the time of admission in January, 1929, his vision was practically gone, and the red count had dropped to 3,600,000 with hemoglobin 75 per cent. Examination at that time showed optic atrophy, which had not been present at the time of the first admission. The Wassermann reactions of the blood and the spinal fluid were negative, and no other cause for the optic atrophy could be determined. Since that time the patient's blood has been kept at a normal level, but there has been no change in vision.

Pallor of the optic disks without signs of atrophy was reported in a small number of ophthalmoscopic examinations.

Cranial Nerve Palsies.—Russell, Batten and Collier[2] were the first and among the few observers to report cranial nerve palsies in combined system disease. In this group of cases presenting pernicious anemia there was one case of a sixth nerve palsy and two cases of seventh nerve palsy that developed in association with the disease.

Nystagmus.—This condition was found in three of this group of cases. Nystagmoid movements were not uncommon.

Speech Disturbances.—One patient was described as having a scanning type of speech; another, speech of a staccato type. A third patient had a transient dysarthria associated with aphasia and subjective sensory changes in the right arm attributed to a cerebral vascular lesion.

Autonomic Disturbances.—While alterations in the pupils were rare, the condition was reported occasionally. No endophthalmus was noted.

Herpes.—While girdle pains, often severe in type, are frequently present, a herpetic condition is not usually associated with involvement of the nervous system in pernicious anemia. Russell, Batten and Collier[2] in their early report described herpes as being present. In one of their cases (case 7) in which there was a hemorrhagic herpetiform eruption, the autopsy showed a cyst occupying the center of the dorsal ganglion. In this series of cases a past history, though not specifically asking about herpes, uncovered a history of this condition in seven cases. Four of these patients suffered from herpes during their acute illness with pernicious anemia, and three of these four later developed degenerative changes in the nervous system. One of these three patients was admitted suffering from a pain similar to a pain she had had five years before, associated with herpes.

Spinal Cord.—The 20 per cent of the cases of pernicious anemia that showed definite combined sclerosis hardly deserve mention. The change brought about by posterior and lateral column degeneration are too well known for further elaboration here.

Peripheral Nerves.—While such change pathologically has been shown by Hamilton and Nixon and by others, there was not sufficient pathologic study to evaluate the question of peripheral neuritis in this series of cases.

Among the patients with cord changes there were five who complained of severe muscle pain, several of whom had pain on deep pressure over what corresponded to the greater nerve pathways. As previously mentioned, a number of patients gave "neuritis," so descriptive of their coursing pain, as the earliest complaint. Other symptoms and signs of neuritis were frequently present; their relationship to a true neuritis cannot be stated.

LABORATORY OBSERVATIONS

The laboratory studies have produced nothing that differentiates the case of pernicious anemia with changes of the nervous system from those without. The chief diagnostic measures, such as blood counts with interpretation of the smear, plus gastric analysis and such adjunctive methods as icterus indexes and hematocrit readings, were used.

Examination of the spinal fluid with normal pressure and dynamics did not give remarkable results. With a rare exception, the cell count ranged from 0 to 4. The globulin was normal except in an occasional case which showed a one plus. The colloidal gold test was almost uniformly quite level.

---

16. Murphy, W. P.: Personal communication to the author.

SUMMARY

A study of 515 cases of pernicious anemia occurring during the years 1913-1930 would indicate that the associated lesions of the central nervous system, present in 20 per cent of the patients, may present a variegated symptomatology and may be disseminated in location.

Bellevue Hospital.

INJECTION OF LIVER EXTRACT IN THE TREATMENT OF PERNICIOUS ANEMIA

H MILTON CONNER, M.D
ROCHESTER, MINN.

The demonstration by Minot and Murphy[1] that the feeding of liver brings about complete remission in pernicious anemia led to the development of liver extracts of various types, of which that of Cohn and his associates[2] is most generally used A search for the effective substance in liver led to partial purification of the material, but these more or less purified substances developed by Cohn and his associates[3] and by West and his associates[4] have proved too expensive to be practical in the treatment of pernicious anemia.

To Gansslen[5] belongs the credit of having first prepared at moderate expense an extract of liver suitable for injection intramuscularly. He injected daily into the gluteal muscles 2 cc, equal in effect to from 200 to 400 Gm. of liver

Castle and Taylor[6] obtained a maximal response in reticulocytes from a single intravenous injection of the extract made from fraction G (343) derived from 100 Gm. of liver. It caused a fall of the blood pressure in a considerable number of cases, but this effect could be obviated by slow injection.

Strauss, Taylor and Castle[7] later produced from fraction G an extract designed for intramuscular injection, of which 20 cc., representing 100 Gm. of liver, was given daily.

Wilkinson[8] produced an extract suitable for intramuscular and intravenous use similar to fraction S of Cohn and free from carbohydrates, lipoids and proteins.

Sturgis and Isaacs[9] recently produced material suitable for intravenous injection

Materials prepared according to the method of one of the foregoing investigators have been used by various workers, notably Schottmuller,[10] Davidson,[11] Harrington and Fleming,[12] Kahler,[13] Meythaler,[14] Aubertin and Voillemin,[15] Schilling,[16] Selander,[17] Störmer,[18] Woldrich,[19] van Leeuwen,[20] Achard and Hamburger;[21] by Billig, West-Watson and Young,[22] Essenfeld[23] and Anderson.[24]

After most of my paper had been prepared, Connery and Goldwater[25] reported on the results of the use of a more concentrated extract, in which 5 cc. represented 100 Gm. of liver; Murphy[26] reported on this preparation, and also on one still more concentrated in which 3 cc. represented 100 Gm. of liver.

CASES STUDIED

I injected liver extract in thirty unselected cases of pernicious anemia. The results in the different series are given separately and are summarized in the table Three cases are not included in the detailed study because of insufficient observation. In one of these the injection of the less concentrated material was discontinued after two days because of the bitter complaint of pain. In one case the patient was under observation only two days after injection of the more concentrated material, and in another doubtful case, the first injection was given only two days before the completion of my paper.

Most patients were observed daily with respect to variations of reticulocytes; certain patients three times daily, during the period of active increase. Hemoglobin, erythrocytes and leukocytes were estimated in some cases daily and in others about twice weekly. Platelets were not estimated in all cases. In some cases, there were approximately weekly estimations of serum bilirubin, iron in whole blood, blood urea, blood sugar and uric acid and iron index (an index of the relative amount of iron in each erythrocyte).

Method of Treatment.—One series of twenty-one patients was treated by the intramuscular injection of material in which 2 cc. represented 10 Gm. of liver

(in this paper called less concentrated material), prepared, in most instances, by one of the standard manufacturing pharmacists according to the method of Strauss, Taylor and Castle, but in a few instances by a preparation made according to their formula by Osterberg in the chemical laboratories of the Mayo Clinic. A second series of three patients was treated by the intravenous injection of a preparation made by one of the manufacturing pharmacists according to the formula of Sturgis and Isaacs, in which 20 cc. represented 100 Gm. of liver. A third series of three patients was treated by intramuscular injection of a more concentrated preparation, in which 3 cc. represented 100 Gm. of liver, and which was developed by Murphy in collaboration with Clark of Lederle & Co. (in this paper called more concentrated material).

Dosage.—The less concentrated material of Strauss, Taylor and Castle was given daily, according to their suggestion, in most instances, 2 cc. (=100 Gm. liver), in several, 4 cc., and in others, various combinations of these amounts. A few patients were given 6 cc. daily for a few injections, with a subsequent reduction to 4 or 2 cc. In several instances, a half pound of liver by mouth was substituted daily for a few days when the supply of liver extract was temporarily exhausted.

The size of the dose seemed to influence somewhat the time of appearance of the peak of increase of reticulocytes and the time of the first appearance of their increase. In most cases in which the peak was reached earlier than the sixth day and the increase was initiated during the second or third day, larger doses had been given. In certain cases there were exceptions, as the larger doses had been given and the increase was initiated and the peak reached at a later date, and in certain other cases the smaller doses had been given and increase was earlier.

The three patients who were given the preparation of Sturgis and Isaacs intravenously were given one injection of 20 cc. (=100 Gm. liver) and one patient was given an additional injection when it appeared that the full effect of the former injection had occurred. Another patient went home four days after the first injection had been given, and the other was operated on. Two of these patients had frank pernicious anemia and one had carcinoma of the stomach associated with pernicious anemia.

The three patients who received the more concentrated preparation intramuscularly were given a small dose (0.5 cc.) to determine if reaction occurred, and in a few hours the remainder of the 3 cc. was given. A second injection of the extract derived from 100 Gm. was given on the second or third or fifth day. Two patients who were given this extract had frank pernicious anemia, and the condition of the other was doubtful; achlorhydria was not present and status epilepticus occurred after injection. One of the two patients had been given the concentrate from 12 cc. of human gastric juice, and because of the subsequent fever and poor general condition, further injections of gastric juice were not made. There was no response in reticulocytes in the ten days following the injection of the small dose of gastric juice, but a marked increase

* For uniformity, if hemoglobin has been measured in grams it has been converted into percentage by multiplying by six.

† In the few cases in which the supply of liver extract was temporarily exhausted, half a pound of liver was given by mouth for a few days instead of 2 cc. of the extract. In estimating the total grams of liver represented by extract given, half a pound of liver is considered as the equivalent in effect of 2 cc. of the extract.

‡ In these cases the reticulocytes were at a high level at the beginning of treatment.

in reticulocytes began fifty-six hours after the injection of liver extract and reached a peak in five days.

Reactions.—The twenty-one patients who were given the less concentrated material intramuscularly, in general did not complain of unpleasant symptoms except soreness, but sometimes they complained of somewhat severe pain at the site of injection. One complained of a "funny" feeling in the head after the first injection. Fever was not noted after injection if it had not been present before. Extensive studies of blood pressure were not made in this particular group in which frequent small doses were given.

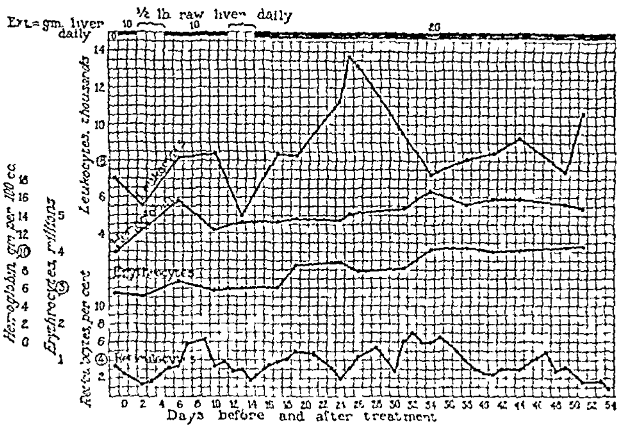

Chart 2.—Results of examination of blood in a case in which liver extract had been given intramuscularly (less concentrated). Failure of reticulocytes to rise to a high point because erythrocytes were relatively numerous at the beginning of treatment may be noted.

Of the three patients who were given intravenous injections, two had a systemic reaction characterized by chill and fever to 100.6 and 103.6 F., and the other patient had fever of 102.8 F. without chill. Two patients, during the period of intravenous injection, complained of an unusual sense of heat, particularly in the face. Studies of the blood pressure were made during and following the intravenous injection, and no significant fall in blood pressure was evidenced.

Of the three patients who were given the more concentrated preparation intramuscularly, one had status epilepticus shortly after the second of two daily injections of 3 cc. (= 100 Gm. liver) had been given following a preliminary dose of 0.5 cc. without reaction. Whether this was due to the injection or to the temporary withdrawal of phenobarbital, because of phenobarbital dermatitis, cannot be determined, but the latter seems likely. This patient had the blood picture of pernicious anemia without achlorhydria, also syphilis of the central nervous system, and was given the injection as a diagnostic procedure. The blood pressure was taken frequently after the injections, and no change of consequence was noted. The other two patients did not manifest noticeable reaction after any injection. All three patients were given the preliminary dose of 0.5 cc., followed in a few hours by 2.5 cc.

Increase of Reticulocytes.—After the intramusuclar injection of the less concentrated material, the reticulocytes usually increased rather rapidly, beginning from two to ten (average four) days after the first administration and reaching a peak in from four to twenty-six (average eight) days, from which there was a rapid fall to normal within a few days (chart 1 and table). In a few cases the reticulocytes increased more slowly, in one complicated case reaching a peak on the twenty-sixth day (charts 2 and 3). The peak of increase of reticulated erythrocytes varied in the different cases from 6.4 to 39.6 per cent and averaged 17.2 per cent (table).

Following the intravenous injections the peak of reticulocytes was reached early, in four and five days (chart 4), and the increase started in thirty-five, fifty-two and fifty-two hours, respectively. The peaks of reticulocyte increase were 35.2, 25.4 and 21.8 per cent (table).

After the intramuscular injection of the concentrated extract, the reticulocytes began to rise at the fifty-fourth hour, the fifty-sixth hour and at a questionable hour and reached the peak of increase in five, five and two days (chart 5). The peaks of reticulocyte increase were 31.8, 38.8 and 7.1 per cent (table). By all methods of specific treatment, the peak of increase of reticulocytes is essentially inversely proportional to the number of erythrocytes at the beginning of treatment.

In most cases the peak of increase of reticulocytes reached or exceeded the theoretical peak, as computed according to the formula of Riddle[27] (table). In a few cases this theoretical peak was not reached, but it is likely that the actual peak of increase of reticulated erythrocytes in these cases was reached in the interval between examinations, which were, as a rule, made daily. In some cases the reticulocytes were estimated three times daily during the few days immediately preceding, during and following the peak of increase of reticulated erythrocytes (charts 4 and 5), and in these the theoretical peak was reached in each case.

Unfortunately, each of the three patients who had the intravenous injections was, for unavoidable reasons, dismissed from hospital at so early a date that little more than the increase of reticulocytes (charts 4 and 6) could be determined; one of these has been observed at weekly intervals since (chart 6), and she returned to the hospital on the thirteenth day for a second intravenous injection. It was desired to see how long the effect of one injection would last so the second dose was not given until the increase of reticulocytes had entirely subsided, and a third dose has not yet been given because the level of erythrocytes and hemoglobin continued to increase thirty-four days after the last injection.

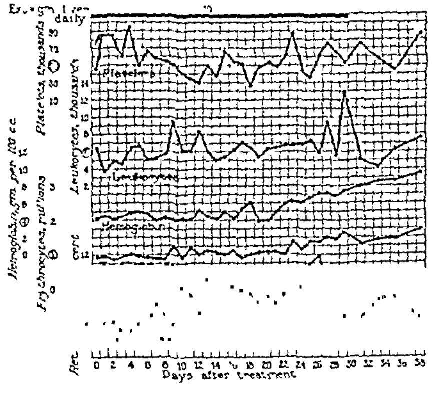

Chart 3.—Results of examination of blood in a case of pernicious anemia complicated by decompensated heart disease, while less concentrated liver extract was being given intramuscularly. Failure of reticulocytes to reach a peak for twenty-six days and the slight increase in erythrocytes may be noted. Necropsy showed typical changes of pernicious anemia in bone marrow

One of the three patients in this group also had carcinoma of the stomach. As soon as a rapid increase

---

27. Riddle, M. C.: Pernicious Anemia: Blood Regeneration During Early Remission, Arch. Int. Med. 46:417 (Sept.) 1930.

of reticulocytes was demonstrated, as additional evidence of the existence of pernicious anemia in association with carcinoma, a transfusion was given and operation performed. A large carcinoma of the stomach was found, but could not be removed. This rapid increase of reticulocytes with liver extract is further proof of the occasional coexistence of pernicious anemia and carcinoma of the stomach. I have observed several of such cases.

Increase in Hemoglobin, Erythrocytes, Leukocytes and Platelets.—The erythrocytes on the whole increased the more rapidly the lower their level at the beginning of treatment. The platelets increased in three fourths of the cases in which they were estimated. See table and reprints.

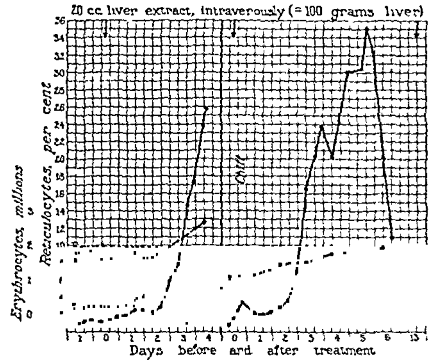

Chart 4.—Level of reticulocytes and erythrocytes in cases of pernicious anemia in which liver extract was given intravenously. Reticulocytes were counted three times daily during period of active increase. Peak on fourth (probable) and fifth day, and beginning increase soon after injection may be noted.

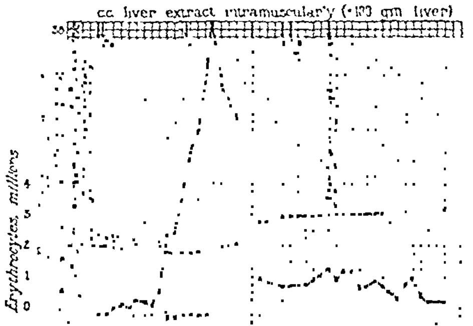
Morphology of Blood.—The changes in morphology of the blood were studied more carefully in cases in which the treatment was intravenous, and in those in which the more concentrated preparation was given intramuscularly. In all cases there was definite macrocytosis and well marked anisocytosis in the beginning. In most cases the so-called pernicious anemia neutrophil was present in the beginning with a shift of the polymorphonuclear leukocytes to the right. A few days after treatment was instituted the macrocytosis increased in some instances, and if this had not been well marked before treatment, it often became evident. As the condition of the blood improved, the macrocytosis usually almost completely disappeared. With the effect of treatment, the right shift in the leukocytes usually partially or completely disappeared and the so-called pernicious anemia neutrophil might or might not be entirely absent. Polychromatophilia, which was present in some degree in all cases of severe anemia, disappeared or diminished as improvement occurred. Basophilic stippling, if present in the beginning, usually disappeared. Eosinophilia was observed in only two cases during treatment. In one case the value was high (4.6 per cent) at the institution of treatment, and increased to 10.2 per cent. In the other, the eosinophils constituted 15 per cent of the total number of leukocytes at the time of institution of treatment. This patient had eaten a small amount of raw liver prior to my examination, but it seemed unlikely that the amount had been sufficient to produce eosinophilia of this degree.

Chemical Constituents of the Blood.—The changes in the chemical constituents of the blood were essentially the same in patients treated by the three different methods (chart 9). There was decrease in the bilirubin of the serum, usually to about half the original amount, the iron in the blood increased, and the iron index,[28] which apparently is always high in pernicious anemia in relapse, decreased toward normal. There was no significant change in the sugar, the uric acid or the urea of the blood.

Effect on Symptoms.—The effect of all preparations on the general symptoms was essentially the same as that obtained by the use of liver or liver extract taken by mouth, but on the whole it seemed to be brought about more rapidly; of the three methods, the intravenous administration seemed to bring about the most rapid improvement, and next to it the more concentrated material injected intramuscularly. The strength rapidly increased, the general well being of the patient was markedly enhanced, the appetite soon returned, the subicteric color of the skin and sclera disappeared, the gastro-intestinal symptoms usually subsided rapidly, diarrhea, when present, ordinarily disappeared and glossitis soon subsided.

Effect on Neurologic Disorders.—I have not noticed from the injection of any of these preparations a definite advantage over the effective materials given orally in cases of involvement of the nervous system. None of the patients among the two small groups treated by intravenous injection and by the more concentrated material intramuscularly had serious neurologic disorders. There were, however, five patients with severe neurologic involvement in the group treated with the less concentrated material, and two had moderately severe involvement. The five patients had severe combined sclerosis and were unable to walk. All but one of this group of twenty-one patients complained of numbness and tingling in the hands or feet at some time in the course of the illness. In most instances when this was the sole manifestation of neurologic involvement, symptoms improved or disappeared. However, when the symptom occurred as a part of marked combined degeneration, little improvement seemed to occur. One patient, whose condition was moderately severe, was unable to write and walked with considerable difficulty before he was put under treatment. At the time he left the hospital, twenty-



*Reticulocytes not above 15% in these 9 days before liver extract

Chart 5.—Level of reticulocytes and erythrocytes in cases of pernicious anemia in which liver extract was given intramuscularly (more concentrated). Reticulocytes were usually counted three times each day. The second case is a doubtful one without achlorhydria but with blood picture of pernicious anemia. Peak of reticulocytes in five days in first case and failure to increase much in second case, partially because reticulocytes were high at the beginning and partly because erythrocyte level was high, may be noted.

---

[28] Murphy, W. P.; Lynch, Ralph; and Howard, Isabel M.: The Value of Determinations of the Iron Content of Whole Blood, Arch. Int. Med. 47:883 (June) 1931.

two days later, he was able to walk without a cane and to write with some difficulty. A patient with moderate involvement of the nervous system did not improve in the seven days in hospital, but an answer to a questionnaire stated that he had improved considerably since going home. One patient with severe involvement of the nervous system was able to walk with great difficulty when he came to the hospital and was unable to walk when he left, although there was a satisfactory improvement in the condition of the blood. Another patient with severe involvement of the nervous system was entirely bedridden during her stay of seven days in hospital; one was entirely bedridden during the period of sixteen days of hospitalization; one with severe neurologic involvement made little, if any, improvement. One patient who had severe involvement of the nervous system following operation for carcinoma of the stomach did not improve under observation in hospital for ten days, but in answer to a questionnaire stated there was a little improvement since he went home.

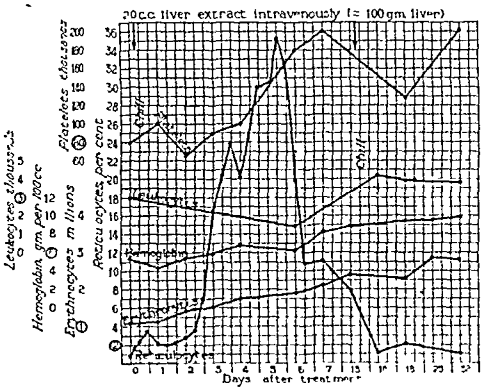


Chart 6.—Results of examination of blood in cases of pernicious anemia after intravenous injection of liver extract. Reticulocytes were counted three times a day.

It is possible that a more marked beneficial effect may occur as the result of much more prolonged treatment by the injection of liver extract, and that lack of good results in most cases of severe involvement of the neurologic system may be due to the comparatively short time the patients received the injections.

Effect of Complications on Result of Treatment.—Complications of various kinds occurred in a number of cases, but did not, as a rule, appreciably affect the progress of the recovery. Perhaps, in one case in which neurologic changes were severe, mild bronchopneumonia retarded the response to treatment. Another patient had mild bronchopneumonia, and there was fever during most of the patient's stay in the hospital, but without apparent effect on regeneration of erythrocytes. The peak of reticulocyte increase, however, in this case failed to reach the theoretic peak by a considerable degree. In two cases syphilis of the central nervous system (besides that in the doubtful case without achlorhydria) did not seem to affect the rapidity of response. In two cases there was probable cholecystitis; in one of these no effect on the increase in reticulocytes or erythrocytes seemed to occur, whereas in the other there was very slow and moderate response of reticulocytes and erythrocytes. This, however, was in the case in which pneumonia and severe neurologic changes were also present, which latter did not respond to prolonged treatment (fifty-one days) (chart 2). One patient had carcinoma of the stomach, for which he was operated on, and during his stay in the hospital, following operation, the anemia and the neurologic changes rapidly became more intense. This patient also had a cord bladder; there were two other such cases in the group. This complication, however, did not seem to influence appreciably the response to treatment. One patient had angina pectoris with coronary sclerosis, urticaria of the skin, probable abdominal urticaria and low basal metabolic rate. There was, however, a moderately rapid increase in erythrocytes, but the increase of reticulocytes failed to reach the theoretic peak by almost half. One patient had marked vertigo, nausea and nystagmus which subsided after improvement occurred in the blood. Two patients had hemorrhoids, two nontoxic adenomas of the thyroid gland, three had chronic prostatitis, one patient had hay fever, one optic atrophy, one tuberculosis of the spine, one chronic tonsillitis and one grand mal (besides the doubtful case without achlorhydria), none of which seemed to influence the speed of recovery. One patient had fever of unknown cause for three weeks, and a cord bladder; it is probable that pyelitis resulted therefrom. Cystoscopic examination was not deemed desirable. There was a good reticulocyte response with a peak higher than the theoretic peak and a very satisfactory increase in erythrocytes, but no improvement in the neurologic condition. Some patients had several of these complications combined.

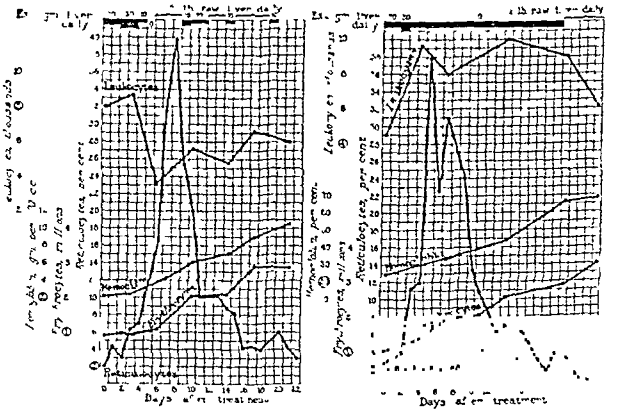

Chart 7.—Results of examination of blood in cases of pernicious anemia in which liver extract (less concentrated) was given intramuscularly. In one case, raw liver was given when the supply of extract became temporarily exhausted, and in the other, raw liver was given during the last five days in hospital. High reticulocyte peak and rapid increase in hemoglobin and erythrocytes may be noted.

In one case there was a typical blood picture of pernicious anemia with achlorhydria, high hemoglobin index and volume index and indefinite complaint of sore tongue. Daily injection of the extract derived from 10 Gm. of liver did not cause reticulocyte response for eight days, and there was practically no increase in erythrocytes from the original level of 1,000,000 cells for several weeks (chart 3). Later, the reticulocytes rose to 12 per cent and the erythrocytes to 1,700,000 but further increase could not be obtained. The patient had cardiac enlargement with severe cardiac symptoms, particularly dyspnea and edema. In spite of daily intramuscular injection of 2 cc. of the less concentrated extract she died from cardiac failure. At necropsy, in addition to other evidence of pernicious anemia, hyperplastic marrow of all the bones examined, including the shaft of the femur, was found. This was in a patient with senile dementia confined to the state hospital, who was treated in collaboration with Dr. Everts of that institution.

Other Treatment.—Transfusion was deemed necessary in only one case, possibly because the lowest initial level of erythrocytes was 880,000. Three of the patients were given dilute hydrochloric acid; one patient was given a cod liver oil concentrate and yeast, and two patients were given food rich in vitamins, including yeast and cod liver oil or its concentrate. One patient two years previously had been given raw swine stomach at the clinic with good results, but while taking this in an amount ordinarily considered adequate she had a relapse, from which recovery was brought about by the use of extract of fish liver. Later, when taking this extract, another relapse occurred during which a very severe neurologic syndrome developed. The blood responded satisfactorily to the daily intramuscular injection of 4 cc. of the less concentrated liver extract, but there was little, if any, effect on the neurologic symptoms.

One patient had formerly been treated successfully by means of a diet rich in vitamins containing a small amount of liver. She had become careless and had practically discontinued the diet, after which she had a relapse with severe neurologic symptoms. In spite of satisfactory improvement in the blood obtained by the intramuscular use of the less concentrated liver extract, from 2 to 4 cc. daily, while in the hospital there was little, if any, improvement of neurologic condition.

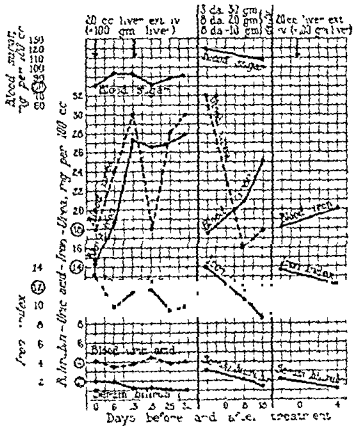

Chart 9.—Results of chemical examination of the blood in cases of pernicious anemia in which liver extract was given intravenously and less concentrated extract intramuscularly. Decrease in serum bilirubin and iron index and increase in iron of whole blood in all instances may be noted. Significant change in sugar, urea or uric acid was not observed.

One patient had formerly been given desiccated hog stomach and had a relapse while taking what would otherwise be considered an adequate dose of 30 Gm. daily; he made rapid and satisfactory response to intramuscular injection of the less concentrated liver extract.

One patient, prior to the administration of the less concentrated liver extract intramuscularly, had been given cooked oysters, a half pound daily, for fourteen days. During the administration of the oysters the reticulocytes had increased from 1.6 to 7.2 per cent. Following the administration of liver extract intramuscularly, however, there was a second increase to 18.4 per cent on the eighth day after the first injection.

Subsequent Treatment.—All of the patients who received the less concentrated preparation intramuscularly were sent home to use liver, liver extract or raw or desiccated stomach by mouth. It did not seem wise to have them make their own injections of the liver extract. Because of this fact, it has been difficult satisfactorily to evaluate the effect of the injection method on the neurologic changes in pernicious anemia, as most of the patients did not continue the treatment long enough to bring about marked change, or any change in some instances. Two of the patients who received extract intravenously were instructed to use liver at home, and the other patient is still being observed without further treatment after two injections of 20 cc. (100 Gm. liver) with an interval of thirteen days. The patients treated with the more concentrated material are still under observation in hospital.

Maintenance Dose.—As my patients were given the injections only during their stay in hospital and were given oral treatment when they were sent home, any statement regarding maintenance dosage would necessarily not be based on first-hand knowledge.

COMPARISON OF THE THREE METHODS

The results obtained by the use of the less concentrated preparation by frequently repeated intramuscular injections are not so striking as those obtained by the intravenous injections or by the intramuscular injections of the more concentrated material. The reactions with the less concentrated preparation were negligible whereas those that occurred from the intravenous injection or in one case the more concentrated material intramuscularly, were much more severe and in some instances rather alarming. The question, of course, arises whether one is justified in producing any considerable reaction by the injection of the larger doses when the smaller more frequently repeated injections are just as efficacious in the long run. There arises also the question as to whether it is not better to stimulate the bone marrow gradually by means of smaller doses than more intensely at longer intervals by injection of more concentrated material. However, the frequently repeated injections are too expensive unless one can send the patient home to carry on the injections himself, which does not seem wise. All in all, it seems quite likely that the injection treatment of choice consists of the intramuscular use of the more concentrated material, an adequate amount of which can be obtained at a comparatively small cost.

COMPARISON WITH ORAL METHOD OF TREATMENT

Since, in our experience, the neurologic changes have not responded appreciably more satisfactorily to the injection treatment (although admittedly treatment was too short to permit a satisfactory opinion) than to liver, liver extract, raw stomach, desiccated hog stomach or diet selected for its rich content of vitamins, each of which is given by mouth, it seems unlikely that the injection treatment can entirely supplant treatment by the oral method, particularly among those who do not object to the use of liver or raw stomach. Pork or beef liver and stomach can be bought at moderate cost. It may be open to question, too, whether the liver extract has all of the beneficial properties of raw liver, raw stomach or desiccated stomach. It is likely that the injection treatment will be of greatest benefit to patients who are extremely ill, patients who have extreme anorexia and are unable to take liver or other effective substance by mouth, patients who are vomiting a great deal, patients who particularly dislike liver or any of the other effective materials, and the very rare patient who manifests symptoms of gout as a result of the administration of liver.

SUMMARY

Thirty patients with pernicious anemia were given liver extract by injection. Twenty-seven were studied in hospital. Twenty-one patients received extract intramuscularly in which 2 cc. is derived from 10 Gm. of liver, and the dose of which was 2 to 6 cc. daily. Three received extract intravenously in which the dose of 20 cc. was derived from 100 Gm. of liver. One or two doses were given in hospital. Three patients were given extract intramuscularly in which the dose of 3 cc. represented 100 Gm. of liver. Two doses were given one, two and four days apart, after a preliminary dose to determine if reaction occurred.

The extract from a very small amount of liver produces maximal effect.

The effect on reticulocytes, hemoglobin, erythrocytes and other blood elements and general symptoms is similar to but more rapid than those produced by oral treatment.

The effect on neurologic symptoms cannot be properly evaluated in this series because the patients were sent home to receive treatment by mouth or were not observed long enough to permit any opinion; however, the results obtained suggest that the effect in severe cases will continue to be unsatisfactory, as in cases in which the oral method was used.

Untoward symptoms, except pain, did not occur in cases in which intramuscular injection of the less concentrated extract was given daily. Chills occurred in two cases and fever in three cases in which intravenous injections were given. Reaction was not directly attributable to intramuscular injection of the more concentrated extract, but in one case status epilepticus occurred after the second of two injections in a case of epilepsy and syphilis of the central nervous system.

ABSTRACT OF DISCUSSION

Dr. John H. Musser, New Orleans: There is no doubt that there are certain types of patients with pernicious anemia to whom it is occasionally advisable to give liver by some method other than by mouth. I was a little worried, until Dr. Conner's last sentence, to know the reason why he had such a considerable series of patients to whom he had given this preparation. I was not worried in the sense that I feared he was going to give the preparation to all his patients, but why he had such a group of patients with severe anemia. It seems to me, of course, that the great merit of his presentation was that liver extract is available for intravenous use. I want to stress that point. I was rather afraid that the idea would get about that liver is best administered by injection. I think it would be a great mistake if such an impression should be broadcast throughout the medical profession in this country. Undoubtedly the great majority of patients with pernicious anemia will get along satisfactorily and will have a proper reticulocyte response when the liver extract is given by mouth. I think that is the method of choice in the great majority of instances. Dr. Conner has told of the patient, however, to whom liver extract cannot be given by mouth, and it is to that type only that I think liver should be given intramuscularly. The patient is extremely rare—and I think Dr. Conner will substantiate the statement—to whom the extract should be given intravenously. There are certain inherent dangers in all intravenous medication. I think intravenous medication of this type should be given in the same spirit with which drugs are administered intravenously. It is interesting that pharmacologists and those interested in the administration of animal preparations, such as insulin, are striving most vigorously for methods of administering the drug other than through injection; possibly their efforts at some time will be successful. On the other hand, there is a drug which seems satisfactory in a great majority of instances when given by mouth, and yet people all over the country are interested in this problem of giving parenterally liver extract, or the gastric juice of swine, or whatever it may be, to patients with pernicious anemia. I think it seems rather paradoxical.

Dr. H. Milton Conner, Rochester, Minn.: I believe very much as Dr. Musser does that we are striving to see that the average patient is able to take by mouth what formerly has been given only by injection, for instance, insulin, and that, on the whole, no patient should be treated by injection either intravenously or intramuscularly who can just as well be treated by mouth. Certainly there are some cases in which, as I mentioned last, the injection method seems to me to be distinctly indicated. I am not much in sympathy, however, with the claim of lessened cost. The injection method has been stressed as being much cheaper. It certainly is not cheaper than liver or stomach. Either the raw stomach or raw or cooked liver, particularly beef or pork liver, is very cheap. So if the patient is able to take these I believe they ought to be taken orally rather than in the form of liver extract in frequent injections either intramuscularly or intravenously.

HYPERTHYROIDISM SHOWING CARBOHYDRATE METABOLISM DISTURBANCES

TEN YEARS' STUDY AND FOLLOW UP OF CASES

HENRY J. JOHN, M.D.
CLEVELAND

For several decades writers in this country and abroad have reported the coincident finding of glycosuria in some cases of hyperthyroidism. Joslin and Lahey,[1] in their recent study of 500 cases of disease of the thyroid, reported the occurrence of glycosuria in 38.6 per cent of 228 cases of primary hyperthyroidism and in 27.7 per cent of 83 cases of adenomatous goiter with secondary hyperthyroidism, as compared with only 14.8 per cent in 189 cases of nontoxic goiter and 13.6 per cent of patients without diabetes or any disease of the thyroid gland. In a series of 100 dextrose tolerance tests which I[2] did in 82 cases of hyperthyroidism and 10 cases of colloid goiter, there was a fasting glycosuria in 19 per cent. In table 1 are given the reports of various authors as to the incidence of glycosuria in cases of hyperthyroidism.

Table 1.—*Glycosuria in Hyperthyroidism*

Author	Number of Cases	Percentage of Cases Showing Glycosuria
Marsh	...	2.0
Joslin and Lahey:		
Primary hyperthyroidism	228	38.6
Secondary hyperthyroidism	83	27.7
Nontoxic goiter	189	14.8
Schulze	16	25.0
John: present publication	100	19.0
Bryan:		
Toxic adenoma	244	3.2
Nontoxic adenoma	982	1.0
Exophthalmic goiter	361	1.1

When chemical analyses of the blood began to be generally used, hyperglycemia, either with or without glycosuria, was demonstrated in sporadic cases of hyperthyroidism. A review of the literature showing the incidence of hyperglycemia in hyperthyroidism (table 2) shows a great discrepancy in the findings of different investigators.

Experimental studies on animals made to determine the relation of the thyroid gland to the blood sugar content showed that extirpation of the thyroid gland

---

[2] John, H. J.: Carbohydrate Metabolism in Hyperthyroidism, Endocrinology **11:** 497-581 (Nov.-Dec.) 1927.

leads to a lower blood sugar level, while, on the other hand, the injection of thyroxin, the feeding of hashed thyroid gland to animals or the injection of thyroid extract produces hyperglycemia. In other words, various workers tried to duplicate the clinical finding of hyperglycemia in the syndrome of hyperthyroidism. Many observations regarding the thyroid-blood sugar relation in human beings are recorded.

The incidence of hyperthyroidism among cases of diabetes is comparatively low, as can be gleaned from table 3, the average being 1.68 per cent. A diabetic patient is, of course, subject to the same ailments as is a nondiabetic person. The incidence of diabetes among cases of hyperthyroidism, on the other hand, is a fairly consistent figure, as can be gleaned from table 4, and is nearly twice as high as the general incidence of diabetes.

The present study comprises clinical and laboratory observations made over a period of ten years, including an intensive study made during the period from Jan. 1 1925, to Oct. 1, 1931. During this time, about 9,000 cases of thyroid disease have been seen in the Cleveland Clinic, most of which were cases of hyperthyroidism (exophthalmic goiter, adenoma with hyperthyroidism). Of this group, 620 cases, or 6.88 per cent, showed some degree of nonphysiologic hyperglycemia (fasting or two and one-half hours or more postprandial) either with or without glycosuria. During these years, it has been the practice of my associates and myself to make a routine blood sugar estimation in every new case, as this gave much information about many unsuspected cases of diabetes which would not have been picked up otherwise. Most of the cases, which showed some degree of nonphysiologic hyperglycemia, were then followed up and studied further for a period up to ten years. These data I am offering here.

TABLE 2.—*Incidence of Hyperglycemia in Hyperthyroidism*

Author	Number of Cases	Percentage of Cases Showing Hyperglycemia
Fitz	1,800 *	0.5
Wilder	2,340 *	0.6
von Noorden and Isaac	1,000	0.6
Wilder	1,131 †	2.0
Sattler		3.0
Lund and Richardson	29	3.4
John: present publication	9,000	6.88
John: 1928	3,335	8.5
Mojarova	84	25.3
Flesch		60.7
Geyelin	27	90.0
Total	18,746	

* Exophthalmic goiter
† Toxic adenoma

When the 620 cases showing nonphysiologic hyperglycemia were followed up further, it was found that in some cases the hyperglycemia was present in only the primary examination and that in some others the hyperglycemia disappeared without any medication. Consequently, these cases are not included in my consideration. In some other cases the patients have not been observed for a long enough period to be included in this series. In some cases inadequate data were available, and for that reason they are not included. Intensive observations over a period of from one to ten years were made on 166 cases which alone are included in this special study. All of these showed a definite disturbance of carbohydrate metabolism. The number of years the patients in this series have been under observation is shown in table 5.

By a very conservative estimate, however, I should say that about 200 cases showed what might be called definite hyperglycemia like that of diabetes. In some of these cases the hyperglycemia was purely functional in type and therefore disappeared in a few weeks or months after thyroidectomy on dietary treatment alone or combined with insulin, but—as further experience taught me—the hyperglycemia would not have disappeared in all cases without such treatment. In the total of 620 cases of hyperthyroidism in which hyperglycemia was present, it remained in 30 per cent and disappeared in 70 per cent. This makes the incidence of diabetes in this series of cases of thyroid disease 2.1 per cent, a figure that is close to the average incidence of diabetes in cases of hyperthyroidism as reported in the literature (2.3 per cent). Thus, of this series approximately 200 patients remained diabetic and had to be treated as such, and 35.7 per cent of them are still taking insulin in order to control the diabetic state.

TABLE 3.—*Incidence of Hyperthyroidism in Diabetes*

Author	Number of Cases of Diabetes	Number of Cases with Hyperthyroidism	Percentage
Greeley	614	6	0.97
Joslin and Lahey	4,917	.	...
Primary hyperthyroidism	.	43	0.87
Toxic adenoma	.	28	0.57
Simple goiter		4	0.08
Wilder	1,249		..

Toxic adenoma		22	1.80
Rabinowitch	3,000	24	0.80
von Noorden	1,000	30	3.00
Murphy Moxon	827	8	0.96
		Average	1.68

This summarizes briefly the problem and is an answer to those who try to offer an academic discussion of this subject, which, interesting as it may be from the standpoint of the laboratory, cannot be fully adopted by a clinician who has to treat these patients, many of them for the rest of their lives.

This point is well illustrated by the report of Sattler,[3] who in 1909 collected 56 reported cases in which diabetes was associated with hyperthyroidism. Thirty-seven of these cases had been followed for a sufficient length of time to afford positive information. Of these 37 cases, in 24 (64.8 per cent) there was a fatal termination within comparatively short periods of time, and in 7 cases the patients died in coma.

TABLE 4.—*Incidence of Diabetes in Hyperthyroidism*

Author	Thyroid Disease	Diabetes	Percentage
Joslin and Lahey: total hyperthyroidism	5,908	75	1.26
Primary hyperthyroidism	1,751	43	2.5
Secondary hyperthyroidism	...	28	4.3
Sattler	1,866	56	3.0
O'Day	....	4	.
Fitz	1,800	9	0.5
John: all thyroid diseases	9,000	207	2.3
		Average	2.31

The incidence of diabetes in this special series of 166 cases and its distribution, according to sex and decades, are given in table 6. The highest incidence is in females, as one would expect, since the highest incidence of hyperthyroidism occurs in females. As for the age distribution of the associated occurrence of diabetes and hyperthyroidism, I have tried to discover how it compares with the age incidence of diabetes without hyperthyroidism, and I have found that the two curves run quite parallel, as shown in chart 1. This suggests that hyperthyroidism does not play any important etiologic rôle so far as the age incidence is concerned. Table 7 shows clearly the priority in appearance of hyperthyroidism, which occurred in 85.5 per cent in primary hyperthyroidism and in 51.9 per cent in toxic adenomas, an observation that may have an important etiologic significance.

---

[3] Sattler: Die Basedowische Krankheit, Leipzig, Wilhelm Engelmann, 1909, vol. 1, p. 384.

In table 8 I offer an analysis of the 166 cases in this series in order to show the progress of the patients. After thyroidectomy 55 per cent of the patients improved as far as their diabetic status was concerned, in 15 per cent the diabetic condition remained stationary, and in 30 per cent the patients either required more insulin or, if not taking insulin, it is but a question of time until insulin will have to be administered. As stated, 35.7 per cent of the entire group are still taking insulin.

It is obvious that glycosuria in itself does not tell a great deal regarding the status of the carbohydrate metabolism unless one knows also the blood sugar response to the ingestion of carbohydrates and the level of the renal permeability to sugar. In a series of 100 dextrose tolerance tests which I did some years ago in 82 cases of hyperthyroidism and 10 cases of colloid goiter, 66 per cent of the curves indicated an impaired tolerance. In a larger series of 239 cases of hyperthyroidism which I[4] published in 1930, 63.5 per cent showed an impaired tolerance. Such an incidence is high and ranks as high as obesity (65.6 per cent). The renal threshold, on the other hand, estimated in 180 cases of hyperthyroidism, was low; thresholds for sugar below 180 occurred in 81.1 per cent of the cases. The average renal threshold was 147. The excretion of sugar by a patient with a low renal threshold is usually of little or no significance. The measure of sugar excretion by the application of Allen's paradoxical law,[4a] however, does throw some definite light on the differentiation of glycosuria in this group of cases and is of distinct value, as Rabinowitch has shown. However, I should offer a caution as to any hurried diagnosis until such a case has been followed up over a sufficiently long period for one to make sure of his premises, as no single laboratory functional test should ever be considered as final.

Table 5.—*Length of Observation on 166 Cases of Hyperthyroidism and Diabetes Over a Period of Years (John)*

HEPATIC LESIONS ASSOCIATED WITH HYPERTHYROIDISM

The liver in a case of hyperthyroidism is supposed to be glycogen-poor; it either does not bind dextrose or else lets it go too readily, or there is such an enormous demand for the dextrose in the body that it is rapidly used up and has no chance of being stored in the liver. In an editorial in the *Annals of Internal Medicine*,[5] regarding the hepatic lesions associated with exophthalmic goiter, the author brings out the following points: "Patients dying in exophthalmic goiter show some degree of simple or pigmented atrophy, but the most marked change was the very frequent occurrence of marked diffused fatty degenerative infiltration bearing all the earmarks of a severe toxic process (like the classic phosphorus liver). The heart and the kidneys presented a marked fatty degenerative infiltration." The author explained these changes as being the result of acute disturbances in the oxygenation of the body resulting from or dependent on the syndrome of exophthalmic goiter. "The livers further show at times a peculiar form of chronic parenchymatous hepatitis in the form of lymphocyte infiltration, bile duct proliferation and increase in stroma of the islands of Glisson." To study these changes, Weller[6] studied 44 autopsies on patients who had shown no condition other than hyperthyroidism;

Table 8.—*Analysis of 166 Cases of Hyperthyroidism and Diabetes (John)*

	Percentage
Male	20.0
Female	80.0
Diabetes severe in	31.0
Diabetes mild in	69.0
Hyperthyroidism severe in	35.0
Hyperthyroidism mild in	65.0
After thyroidectomy	
Diabetes improved in	55.0
Of these still taking insulin	23.5
Diabetes more severe in	30.0
Of these still taking insulin	46.0
Diabetes stationary in	15.0
Of these still taking insulin	62.0
All patients still taking insulin	35.7

[4a] The more the carbohydrate taken by a diabetic patient, the less is utilized.

[5] Editorial: Hepatic Lesions Associated with Exophthalmic Goiter, Ann. Int. Med. **4**: 501 (Nov.) 1930.

[6] Weller, C. V.: Hepatic Lesions Associated with Exophthalmic Goiter, Tr. A. Am. Physicians **15**: 71-76, 1930.

his report is shown in table 9, which was presented before the Association of American Physicians in 1930.

Weller summarized his findings as follows:

> A well marked chronic parenchymatous hepatitis was found at autopsy in 22 of 44 selected cases of Graves' disease, while but one case of the same degree of hepatic lesions was found in a control series of the same number of autopsies. In the Graves' disease group, only six showed no evidence of hepatitis while in the control series 30 out of the total of 44 cases showed no hepatitis. The coincidence of hepatitis with exophthalmic goiter is therefore significant and is in accord with clinical observations of the occurrence of functional disturbance of the liver in cases of Graves' disease.

Simonds and Brandes[7] rendered dogs thyrotoxic by heavy thyroid feeding (for from thirty-two to one hundred days). The livers of these dogs were practically devoid of glycogen.

Asher[8] found that in animals made absolutely free from carbohydrate by thyroid feeding and phlorhizin, the addition of fat to the food increased the output of sugar. From this he decided that the hyperthyrotic liver possesses the ability to form glycogen but cannot fix it so that after its formation it gives it up.

Charvát and Gjurič,[9] who studied the problem of carbohydrate metabolism in hyperthyroidism, came to the conclusion that the liver in cases of exophthalmic goiter is the cause of hyperglycemia because it does not bind its glycogen in a stable manner, its glycogen is labile and the tissues burn dextrose well; furthermore, in order to use up as much of the circulating dextrose as possible, the renal threshold in hyperthyroidism is raised.

Table 9.—*Weller's Data*

	Hyperthyroidism	Controls
Number of cases showing no hepatitis....	6	30
Number of cases showing slight or moderate hepatitis	16	13
Number of cases showing well marked hepatitis	22	1

These authors offered as an explanation that in exophthalmic goiter a condition of liver shock is present in which the glycogen-poor liver binds glycogen very loosely and lets go of it easily, whereas the tissues in patients with hyperthyroidism need sugar badly as a ready and excellent supply of energy; moreover, sugar does not burden the organism with any specific dynamic action as do fats and proteins. As the liver through the lability of its dextrose causes a marked hyperglycemia, the renal threshold is easily crossed and theoretically glycosuria should result in all cases. This, however, is not the case, as Charvát and Gjurič have shown, for the threshold rises in order to enable the tissues to use up a greater portion of the dextrose.

In view of their experiments the authors studied the arterial and the venous blood sugar for a period of several hours after the injection of physiologic solution of sodium chloride in normal persons and in patients with diabetes and again in cases of hyperthyroidism. In normal persons they found that without the injection of saline the arterial and the venous sugar fluctuates but inappreciably. After the injection of saline into normal persons, the discrepancy between arterial and venous blood is also slight (chart 2). They said that such an injection is not sufficient to mobilize the sugar, either in the tissues or in the liver.

On the other hand, the injection of saline into patients with hyperthyroidism presents a more interesting picture (chart 2). Here there is a definite dissociation between the arterial and the venous sugar. The arterial sugar rises higher than the venous sugar, which rises but little or may even be decreased. Such an injection causes shock to the liver, to which it answers by releasing its labile glycogen into the circulation. That this is in reality the liver sugar and not the tissue sugar is shown by the fact that the arterial blood sugar rises, whereas the venous sugar is not changed. There is thus a certain surplus in the arterial blood which is caught by the tissues and does not reach the venous blood. It is a well known fact that dextrose itself is the best stimulant for the utilization of dextrose by the tissues. Charvát's former work[10] showed that the burning of dextrose in the tissues of patients with hyperthyroidism is very active.

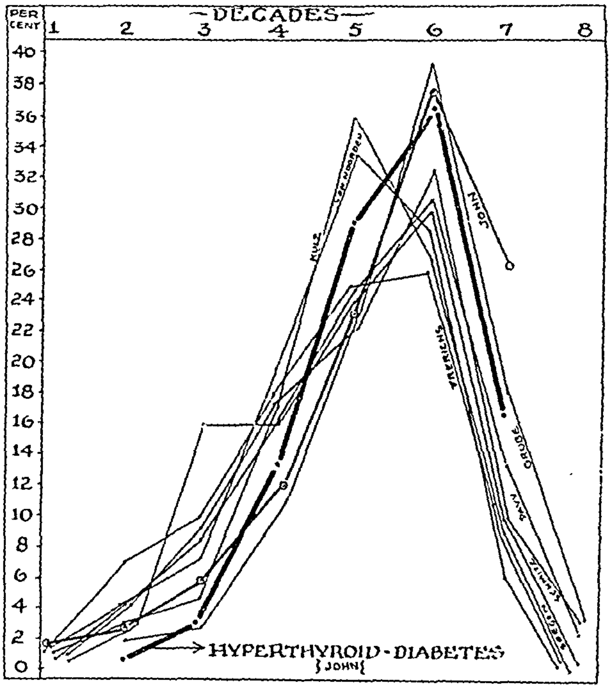

Chart 1.—The incidence of diabetes in various decades according to eight authors.

In the case of diabetic patients the picture is somewhat changed. In such a case the arterial sugar does not rise as markedly as is the case in hyperthyroidism and the curve often approaches that of normal persons. The venous sugar, on the other hand, is higher than the arterial sugar (chart 2). According to Gjurič's view, in cases of severe diabetes the tissue rather than the liver binds the sugar in a labile manner and releases it easily into the venous blood, which consequently is higher than the arterial sugar. In this manner the glycoregulatory disturbance of the patient with hyperthyroidism differs markedly from that in diabetes.

That the liver is not the chief factor in the production of hyperglycemia in hyperthyroidism is suggested by the following points:

1. The incidence of hyperglycemia in hyperthyroidism is too low.

[10] Charvát, J.: Metabolic Reflexes, Časop. lék. česk. **67**: 533-537, 1928.

2. The incidence of hyperglycemia in hyperthyroidism is irregular; severe cases usually show no hyperglycemia; mild cases may show pronounced hyperglycemia. If the liver were the primary factor, the degree of hyperglycemia would be proportionate to the severity of the hyperthyroidism.

3. In general, the renal threshold in patients with hyperthyroidism is low,[4] but the excretion of sugar bears no relation to the severity of the hyperthyroidism. If the storage function of the liver were at fault, glycosuria would automatically disappear after thyroidectomy, but this does not happen. In 35.3 per cent of the 166 cases reported here, the patients have to continue to take insulin, for even though the condition of the liver has improved, the pancreas still does not function sufficiently.

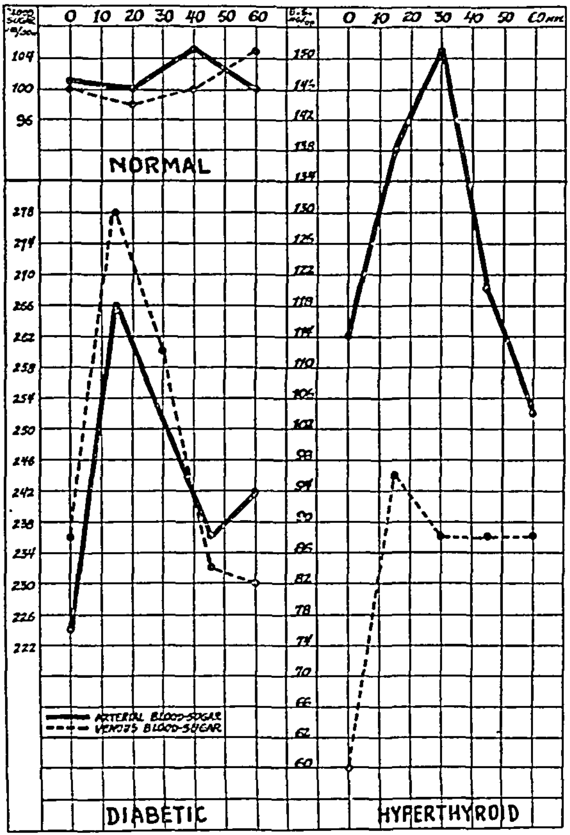

Chart 2.—Curves after the injection of 1 cc. of physiologic solution of sodium chloride per kilogram of body weight (After Charvat and Gjurić)

Ketone Bodies.—Thyrotoxic persons who are given a carbohydrate-free diet for two days show a marked increase of ketone bodies in the blood. In the normal person the fasting value of ketone bodies never exceeds 3.5 mg. per hundred cubic centimeters of aceto-acetic acid and 5.5 mg. per hundred cubic centimeters of beta-oxybutyric acid. In the thyrotoxic patient the ketone bodies rise as high as 16 mg. per hundred cubic centimeters of aceto-acetic acid and 18 mg. per hundred cubic centimeters of beta-oxybutyric acid. The patient with hyperthyroidism has a lowered glycogen reserve available for metabolism.

Levulose.—Strauss[11] first introduced the determination of alimentary levulosuria as a method for testing the liver function. Isaac and Adler[12] showed experimentally that of all the organs and cells of warm-blooded animals only the liver is capable of transforming levulose into dextrose. According to Isaac, the alimentary levulosuria is dependent on the fact that the part of the levulose which is not converted into glycogen or is not burned, in case of functional inability of the liver to convert levulose into dextrose, passes as levulose into the blood and is excreted as urine.

Kugelmann[13] offered the following conclusion: "We can now say with certainty that the thyrotoxic liver not only suffers severe injury in its glycogen depots but has also lost the capacity to change large amounts of levulose into dextrose and to utilize them later." (See chart 3, which represents Kugelmann's experiments along this line.)

Insulin.—Ten units of insulin given intravenously to man causes a rise of blood sugar of from 15 to 20 mg. per hundred cubic centimeters of blood in the first ten minutes, after which it falls. Bürger[14] demonstrated that this primary rise of blood sugar is dependent on the glycogen function of the liver. In none of the cases of exophthalmic goiter studied by the Bürger method by Kugelmann was this initial hyperglycemia seen. This is a further proof of poverty in glycogen in the hyperthyrotic liver.

Rathery, Kourilsky and Laurent[15] have shown that the blood sugar in depancreatized, starved, and starved and phlorhizinized dogs is distributed in the same proportions during the maximum effect of insulin as in normal animals. The discharge of glycogen from the liver is not influenced by its glycogen content. In dogs under similar experimental conditions, the hyperglycemia immediately following the administration of insulin upsets irregularly the relationship between the blood sugar in different vascular areas.

It would seem that with a little help from insulin the liver gradually resumes its capacity to bind more dextrose and keep a more even blood sugar level. Were it the state of hyperthyroidism alone which brings about the functional change that manifests itself in hyperglycemia, then one would expect the degree of hyperglycemia to bear a direct relation to the severity of the hyperthyroidism, and the incidence of hyperglycemia in cases of hyperthyroidism would be greater than it is. This is not so, however, for some of the most severe derangements of carbohydrate metabolism are found in some of the mildest cases of hyperthyroidism, and many of the most severe and even toxic states of hyperthyroidism show no disturbance of carbohydrate metabolism. Insulin brings about improvement in all cases by its direct action, by its protein-sparing action, through its influence on the storage of glycogen, on the diminution of the ketone bodies, or as the result of all four of these. The fact that disturbed carbohydrate metabolism rights itself in only the mild cases suggests that the protein-sparing function may play a rôle in the carbohydrate metabolism.

As for the clinical effect of insulin on hyperthyroidism, one may reason that it perhaps improves the patient's general metabolic condition, giving him a better chance to store glycogen in the liver and thus to combat acidosis; to store glycogen in the heart muscle and thus to give it a better chance to do its work; to spare protein by the increased oxidation of dextrose, and to store glycogen in the muscles and thus eliminate the instability of the organism in general. There is perhaps nothing specific about the action of insulin.

It is a good preoperative measure to give a patient 250 cc. of 10 per cent dextrose made up in saline solution intravenously, together with from 10 to 20 units of insulin, depending on the patient's condition. When the dextrose is buffered with insulin, hyperglycemia does not result even in diabetic cases, as I have shown in my observations on the intravenous administration of dextrose in cases of diabetes and in cases of acidosis as well as in ordinary surgical cases.[16] Such a procedure, therefore, is both logical and helpful, both before and after operation, for the first three days following the operation is the critical period for the patient and a little prevention goes far.

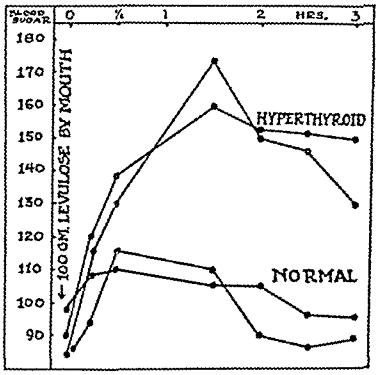

Chart 3.—Blood sugar curves of the administration of 100 Gm. of levulose. (After Kugelmann.)

Postoperative Acidosis.—Acidosis is a well recognized complication of the postoperative course after thyroidectomy. The pulse rate in such cases is high, and the patient can become semicomatose or stuporous immediately after operation. Is the acidosis in these cases of the same type as diabetic acidosis? Diabetic acidosis is due to the inability of the organism to burn dextrose, this in turn producing an incomplete combustion of fats with the resultant accumulation of ketone bodies in the blood stream (acetone, diacetic acid, beta-oxybutyric acid) and consequent acidosis. In uncomplicated hyperthyroidism, however, there is no such inability to burn dextrose, but there are rather an inability to store glycogen and a general increase of the metabolic process, so that all the available carbohydrate, including the glycogen reserve of the liver and muscles, is often utilized with resultant hypoglycemia. Holman[17] cited a case of hyperthyroidism in which the basal metabolic rate was plus 29 and plus 35 per cent, on two occasions. After thyroidectomy the pulse rate rose to between 180 and 250 immediately after operation, this very high rate lasting for sixty hours. Twenty-four hours after the operation the patient was in a semicomatose condition, and her blood sugar at that time was found to be only 48 mg. per hundred cubic centimeters. Dextrose solution, 20 per cent, was administered, and immediately the patient became conscious. Six hours later the patient again went into a deep stupor. She was again given dextrose, and again immediately became conscious. It is clear that in this case the stupor was due to hypoglycemia, a condition similar to the hypoglycemia of an insulin reaction. This is a condition that should be borne in mind. Blood sugar studies during the postoperative period are often of great value as they tell the needs of the patient at that time.

Basal Metabolism.—The relationship of the basal metabolic rate to the dextrose tolerance in a series of cases of thyroid disease is shown in table 10. It will be noted that in 60.6 per cent of the cases analyzed the dextrose tolerance curve was diabetic or prediabetic in type, while the basal metabolic rates ranged from minus 3 to plus 90 per cent. The case in which the metabolism was minus 3, however, was one of simple goiter and not one of hyperthyroidism. In 39.4 per cent of the cases the dextrose tolerance curve was normal in type, and the basal metabolic rate in these cases varied from minus 3 to plus 80 per cent. On the basis of this study it seems evident that the height of the basal rate bears no relation to the carbohydrate metabolism. The mild derangements of the carbohydrate tolerance that have been observed in this series of cases may be but functional disturbances. They may disappear only in part when hyperthyroidism is eliminated either by operation or by other treatment, thus showing that there is something other than the hyperthyroidism that is playing a part.

TABLE 10.—*Relation of Basal Metabolic Rate to Dextrose Tolerance Tests in 66 Cases of Thyroid Disease (John)*

	Normal Basal Metabolic Rate	Increased Basal Rate, Percentage									Total	Percentage

Normal	1	6	5	4	5	2	1	0	2	0	26	39.4

COMMENT

I think that the explanation of the disturbed carbohydrate metabolism associated with hyperthyroidism is not found in the state of hyperthyroidism per se, but that it is due rather to some other factor which I believe is a "diabetic anlage" that was present in the patient before the hyperthyroidism developed; infection or obesity would have brought about the same disturbance. Thus Naunyn,[18] in 1917, made the following statement: "I consider it justifiable to draw the conclusion that the thyroid causes glycosuria only where there exists a predisposition (anlage) to diabetes."

The following statement has been made by von Noorden:[19] "Pure hyperthyroidism in the presence of a fully normal chromaffin system and a normal pancreas will very seldom produce an alimentary and spontaneous transitory glycosuria."

It is possible that in hyperthyroidism, in which one is dealing with such an unstable nervous system, the nervous regulatory mechanism may also enter into the picture. But even so, the same problem is presented. Why is it that hyperglycemia occurs in some of the mildest cases of hyperthyroidism and is not present in many of the most severe cases?

Again one may raise the question whether in hyperthyroidism one may be dealing also with hypersuprarenalism, a condition that is known to produce hyperglycemia. In some of the mild cases in which the hyperglycemia disappears after thyroidectomy, the hyperglycemia might well be due to this cause. However, were the hyperglycemia due primarily to hypersuprarenalism, one would find a much higher incidence of hyperglycemia than is found and this again would be relative to the severity of hyperthyroidism, which is not the case.

[19] von Noorden, C. H.: Zuckerkrankheit und ihre Behandlung, ed. 7, Berlin, A. Hirschwald, 1917, p. 41.

The question that is unsettled today is whether any of the factors mentioned could induce diabetes when there is no "diabetic anlage" to start with. I think not, but it is not known at present, as the background on which to base a proper interpretation of the facts that confront one and with which one has to deal is lacking.

The incidence of diabetes in hyperthyroidism is 2.1 per cent. The incidence of diabetes at large is given as 1 per cent. There is thus a 100 per cent increase of diabetes in cases of hyperthyroidism. I am inclined to think that a big factor here is the question of overeating, which is automatically brought about by the increased metabolism demanding more calories, and as the patient starts losing weight he automatically tries to compensate for this by eating more. This throws a great load on the insulogenic apparatus, which, if normal and with a good reserve, stands it well; if the reserve is small, it easily becomes exhausted and diabetes results. The condition is similar to obesity (overeating), in which, too, the incidence of diabetes is high, and the two are analogous pictures, their end-result being the same, though in one the patient is thin and in the other fat. Also the incidence of diabetes in hyperthyroidism is high from the fifth decade on, when one has to consider the problem of arteriosclerosis and endarteritis, which no doubt are contributory factors to functional changes in the insulogenic apparatus.

The medical problem involved in mild cases of disturbed carbohydrate metabolism is to protect persons with a decreased carbohydrate tolerance, rather than to let them drift along, unprotected, toward diabetes. They should be under surveillance until the physician has satisfied himself that stability has been established. In most of these cases the glycosuria disappears after thyroidectomy and the carbohydrate tolerance is restored to normal; in others, this does not happen. It is important, therefore, to make postoperative examinations in order to determine whether or not the carbohydrate metabolism has been restored to normal, and when this has not happened to institute such measures as are indicated. It is much easier to keep a diabetic patient in the mild stage of diabetes on a mild dietary routine (for that is all that is necessary in most mild cases) than to treat him successfully after a severe stage of diabetes has developed.

SUMMARY

1. No dextrose tolerance curve is specific for hyperthyroidism. That is, a definite diabetic type of curve may be present in a mild case of hyperthyroidism and a normal curve may be present in a very severe case of hyperthyroidism.

2. A single blood sugar estimation, when such a patient is first seen, is no criterion in the evaluation or even a diagnosis of diabetes in such a patient. This serves merely as a lead which should be followed up further and the true state of the patient determined. Even a high blood sugar may be just an incidental finding that clears up quickly, and another much lower blood sugar may persist as a definite diabetic condition.

3. The diagnosis of diabetes in cases of hyperthyroidism can be made only when such a patient has been studied over a sufficiently long time to determine a persistence of the defective carbohydrate metabolism. Without such a time element, many faulty diagnoses of diabetes are bound to occur.

4. Thyroidectomy lowers the total metabolism and in consequence improves the carbohydrate tolerance. In cases in which little or no improvement follows thyroidectomy this is due to the fact that lack of proper diabetic treatment or insufficient treatment has followed the operation, or else that intercurrent infections have produced further damage to the pancreas.

5. If diabetes develops after thyroidectomy, it is due either to other extraneous factors such as produce diabetes in other cases or to the fact that an insufficient amount of thyroid tissue has been removed and an active stage of hyperthyroidism persists. In the latter case, when more of the gland is removed, the diabetes is improved.

6. Hyperthyroidism plays a fundamental etiologic rôle in the disturbances of endocrine equilibrium in cases with a diabetic anlage in which diabetes can be precipitated. The factor here may be the heavy ingestion of food which accompanies active hyperthyroidism, thus placing a heavy load on the insulogenic function.

7. Glycosuria and hyperglycemia (either fasting or more often two and one-half hours after a meal) are not uncommonly present in hyperthyroidism. When found they should not be disregarded, but their significance and their relationship to the carbohydrate metabolism should be determined by appropriate tests.

8. The presence of hyperglycemia two and one-half or more hours after a meal, if it persists, is usually an expression of an insufficient insulogenic function.

9. The intervention of the menopause in a case of hyperthyroidism may cause hypertrophy of the islands of Langerhans with the resultant cure of a coincident diabetes. This probably, however, is a rare occurrence, for but few cases are reported in the literature (Rohdenburg [21]).

10. The glycogen depletion of the liver in hyperthyroidism increases the tendency to acidosis and makes a mild case of diabetes temporarily appear as a severe case. This factor is aggravated in cases in which diabetes is present. The ingestion or the intravenous administration of dextrose before or after operation, with or without insulin, according to the indication in the individual case, would seem to be a logical procedure. The factors that influence the glycogen depletion are probably the following:

(*a*) Toxic influences which directly affect the parenchyma of the liver cells.

(*b*) A high metabolic rate which causes increased consumption of carbohydrate and depletes the insulogenic stores, with resultant depletion of the glycogen store in the liver. Such a depletion is also shown in uncomplicated cases of hyperthyroidism which do not show a high blood sugar.

11. Hypersuprarenalism may also play a part in the production of hyperglycemia.

12. Patients with hyperthyroidism in whom a frank diabetic condition of severe type is not present, but

---

[21] Rohdenburg, G. L.: Spontaneous Disappearance of Diabetes, Endocrinology 6: 519-522 (July) 1922.

merely a mild degree of disturbance of the carbohydrate metabolism, may have but "functional" diabetes or again they may have cases of early diabetes. If appropriate treatment is not given, a frank diabetic state may develop.

13. The administration of thyroid preparations is not without danger. It may precipitate hyperthyroidism, and may even produce diabetes.

14. In my series of 100 dextrose tolerance tests in 82 cases of hyperthyroidism and 10 cases of colloid goiter, fasting glycosuria was present in 19 cases and absent in 81 cases. Sixty-six per cent of the curves indicate an impaired tolerance.

15. From the observations of these patients it would appear that the renal permeability is decreased in the active stage of hyperthyroidism. The renal threshold for dextrose was below 120 mg. per hundred cubic centimeters of blood in 35.6 per cent of the patients studied. The average renal threshold in cases of hyperthyroidism was 147 mg. per hundred cubic centimeters of blood.

OLFACTORY DISTURBANCES

ERNEST M. SEYDELL, M.D.
WICHITA, KAN.

In spite of the tremendous advance made in almost every branch of otolaryngology, the knowledge of olfaction remains, with few exceptions, the same as it was thirty years ago. There are many reasons for this, one of the most important being that it is possible to investigate this sense only from a subjective standpoint. Olfaction being regarded as a nonimportant sense, few rhinologists are sufficiently interested to publish case reports and interesting observations and to follow these with postmortem examinations. Until this is done, the true story of olfaction will never be written.

There is no absolute norm in olfaction, as it may be determined either in different persons or in the same person at different times. There is a constant physiologic variation in the acuity of the sense of smell as well as a great variation in the sense feeling produced by an odor in different persons at the same time, or in the same person at different times. In addition to these physiologic variations, there are a number of conditions which vary sufficiently from the normal to be termed pathologic, and it is these that I wish to discuss at this time.

The Specht classification of respiratory disturbances is:

1. Respiratory disturbances
    - *A.* Quantitative disturbances
        1. Hyposmia
        2. Anosmia
    - *B.* Qualitative disturbances
        1. Cacosmia
2. Essential disturbances
    - *A.* Quantitative disturbances
        1. Anosmia
        2. Hyposmia
        3. Hyperosmia
    - *B.* Qualitative disturbances
        1. Parosmia
3. So called functional disturbances
    - Hallucinations

The Specht classification has the advantage of giving a good perspective of the subject, but would be difficult for listeners to follow. I have therefore adopted this simplified outline:

1. Quantitative disturbances
    - *A.* Respiratory
    - *B.* Essential
    - { Hyperosmia, Hyposmia, Anosmia }
2. Qualitative disturbances
    - *A.* Respiratory
    - *B.* Essential
    - { Cacosmia, Parosmia, Agnosias, Hallucinations }

It must be remembered that any classification of olfactory disturbances has only relative value since transitions and combinations are frequent. Even the border zone between the normal and pathologic is impossible to define in all cases.

QUANTITATIVE DISTURBANCES

Hyperosmia.—A person may be able to perceive certain odors in a much less concentrated form than other persons can, while for other odors his sense of smell may be normal or subnormal. It is not certain whether this is a congenital or an acquired condition. The congenital form is probably more frequent. A hyperosmia for all odors is a rare condition and is usually the result of the use of certain drugs, i. e., strychnine and cocaine. With the latter drug it is, at least in part, caused by the shrinking effect of the cocaine on the mucous membrane of the nose, the access to the olfactory area thus being facilitated. The late effect of cocaine is that of a severe olfactory depressant.

Ponzo[1] has shown that benzoyldimethylaminomethylpropanol hydrochloride also produces a hyperosmia even though it causes a swelling of the mucous membrane of the nose. Hyperosmia is also supposed to occur in pregnancy and in hysteria. Von Skramlik[2] and others have stated that this is not a true hyperosmia but is due to the neurotic condition of the patient.

Hyposmia.—In hyposmia, every degree of impaired olfactory function from the slightest defect to complete anosmia may be found. The temporary hyposmias which follow infectious diseases and nasal infections are of frequent occurrence. Not all patients recover completely. Their prognosis depends in part on the severity of the causative infection and is also influenced by the presence of such nasal complications as sinus infection. The pathology of this condition is unknown.

Anosmia.—Anosmia may be unilateral or bilateral. The condition may be temporary or permanent, partial or complete. One may differentiate between a respiratory and an essential anosmia. In the former type of anosmia, the respiratory cleft leading to the olfactory area is cut off either by pathologic conditions or by accidental injury. As a subdivision of the respiratory type may be mentioned the gustatory anosmia which is caused by an obstruction of the choana.

The essential anosmias are due either to a disease of the olfactory mucous membrane or to some intracranial pathologic condition or accident destroying the olfactory nerves or center. Anosmia may even be congenital. In this case, there is usually an absence of the olfactory nerves.

Read before the Section on Laryngology, Otology and Rhinology at the Eighty-Third Annual Session of the American Medical Association, New Orleans, May 13, 1932.

[1] Ponzo, Mario: Ueber die Wirkung des Stovains auf die Organe des Geschmack, Arch. f. d. ges. Psychol. **14**: 385-436, *p. 427, 1909.*

[2] von Skramlik, Handbuch der Physiologie der niederen Sinne, Leipzig, Georg Thieme, 1926.

Respiratory Anosmia: Under this heading may be specified as an etiologic factor any condition that causes an obstruction of one or both nostrils, i. e., nasal foreign bodies, rhinoliths, crusts, new growths, benign or malignant, deflection of the septum, enlarged turbinates or any other condition that prevents the inspiratory air current from coming in contact with the olfactory areas.

It has been noticed that destructive lesions of the ala nasi, when no involvement of the olfactory mucous membrane has taken place, are usually accompanied by some degree of anosmia. In these cases, the inspired air is not directed to the olfactory region. In a similar way, anosmia may occur following facial paralysis and collapsed alae nasi. In the acute and chronic sinus infections, there is frequently a combination of the respiratory and the essential types.

It is possible that an atrophy of disuse may develop in long-standing occlusion of the nasal passages, but this is by no means the rule.

Essential Anosmia, Type 1: It is probably futile to divide the essential anosmias into those which result from some lesion of the olfactory nerves and into those of central origin, because it is impossible to localize the lesion causing the olfactory disturbance except in those cases in which an involvement of other intracranial structures helps one to localize the site of the lesion. Nevertheless, one must hold to this classification for theoretical reasons.

If one accepts the theory that smell is the result of osmotic processes, it becomes self-evident that the slightest change in the chemistry of the cell plasma or in the cell walls must influence this process. It is therefore easily understood that an anosmia may result from fevers, any change in the amount of nasal secretion, extremes of temperature, dust, etc. In most of these conditions, the anosmia is temporary, but when an atrophy of the mucous membrane of the nose takes place, as in ozena, atrophic rhinitis or syphilis, it often becomes permanent.

Influenza is one of the most common etiologic factors, especially when it is associated with sinus infection. In these cases, the anosmia may be of a temporary nature or may become permanent; in other cases there is a partial recovery, with some or many of the smell qualities being lost.

In people with vitiligo and in albinos, olfactory disturbances have been repeatedly noticed. They were formerly supposed to be due to a lack of pigment in the olfactory mucous membrane; more recently, however, Schwartz[3] in investigating this question found a normal amount of olfactory pigment in albino squirrels, guinea-pigs, rats and mice.

Anosmia also may result from the toxic action of certain drugs, i. e., vapors of osmic acid, sulphuric acid, fluoric acid, sulphur, fumes arising from the manufacture of rubber, alcohol, tobacco, chloroform, ether, morphine, cocaine, phenol, etc. The deleterious effect of these chemicals may be due to their local action on the olfactory mucous membrane or to their toxic action after absorption into the blood stream. It is a well known fact that the application of cocaine to the olfactory area produces at first a hyperosmia due to the shrinking of the mucous membrane of the nose, thereby making the olfactory area more accessible. Later, an anosmia develops, the duration of which coincides in a general way with the time of anesthesia of the mucous membrane. Prolonged use of cocaine causes a degeneration of the mucous membrane with resulting permanent anosmia.

Fatigue Anosmia: Fatigue anosmia probably is usually of peripheral origin. It is characterized by the loss of certain smell qualities and usually is due to the exposure of the olfactory apparatus either to intense or to prolonged stimulation. Whether this fatigue is of peripheral or central origin is not known. Fatigue anosmia may be either temporary or permanent.

Traumatic Anosmia: Traumatic disturbances of smell may arise from direct injuries to the olfactory region of the nose or may result from injury to other portions of the head in which the olfactory nerve or bulb is injured indirectly. The most common causes are skull fractures in which the cribriform plate is involved. Fractures of the root of the nose are also prone to injure the olfactory apparatus. Anosmia has followed a submucous resection of the septum in which the perpendicular plate of the ethmoid was destroyed.

Congenital Anosmia: Congenital anosmia is a rare condition. Zwaardemaker stated that it is usually found in persons who have a deformity of the skull, with an absence of the lamina cribrosa. These patients frequently have other abnormalities, such as cleft palate and malformations of the septum. It is possible that many of these cases may be overlooked since it is impossible to make accurate olfactometric examinations in children.

Senile Anosmia: It has been shown that in the aged the sense of smell gradually diminishes, but complete anosmia is rare. This senile olfactory disturbance is frequently accompanied by parosmia.

Essential Anosmia, Type 2 (Intracranial): Here one must consider all of those diseases and new growths that interfere with the olfactory tract and those which involve the olfactory centers. These structures may also suffer from increased intracranial pressure from a distant source, especially that secondary to growths or abscesses in the temporal lobes, and also from neoplasms, etc., in the frontal and occipital lobes and in the pituitary body. New growths, as well as syphilis, tuberculosis and meningitis, if they occur along the floor of the frontal fossa, are especially prone to disturb the olfactory apparatus. Even hemorrhages in this region have caused olfactory disturbances. Anosmia may also follow softening of the brain and has been reported in tabes, dementia paralytica, paralysis agitans, myelitis, polyneuritis, myatonia congenita, syringomyelia, hydrocephalus, diseases of the middle cerebral artery, epilepsy, insanity and commotio cerebri.

Diagnosis of Anosmia: Owing to the apparent difficulties met with in making olfactometric examinations, few rhinologists have given serious consideration to olfactory disturbances. A fairly accurate examination of the sense of smell can be made even without special apparatus. Proetz[4] has devised a method that is both simple and accurate. The method of Bornstein[5] has an added advantage in that it includes the testing of the sense of smell, nasal taste, taste and the nasal tactile sense.

Bornstein has advocated that a complete test of these sensations should be made in each case: first, because the laity frequently confuse the sense of olfaction with that of taste (glossopharyngeal and sensory facial) and also that of nasal tactile sense (trigeminus) with that of olfaction; second, because the findings are of great value in making a differential diagnosis between pathologic and functional conditions. The reason for the complete examination will again be referred to under differential diagnosis.

[5] Bornstein, quoted by Laemmle: Ueber Geruchsstörungen und ihre klinische Bedeutung, Arch. f. Ohrens-, Nasen- u. Kehlkopfh. **130**: 22-42, 1931.

Bornstein's (Geruchsleiter) Clinical Olfactometric Examination.—The substances used in the examination are so selected that they range from those having a very weak olfactory potency and gradually increase to a high potency. Bornstein has also taken into consideration the fact that tactile and taste components play an important rôle in the recognition of odors. His testing odors are selected from pure smell substances.

1. Wax
2. Stearin
3. Soap
4. Rosewater
5. Heliotrope
6. Bitter almond water
7. Turpentine
8. Spirit of camphor
9. Oil of lavender
10. Amyl acetate
11. Rectified oil of birch tar, N. F.
12. Anise oil
13. Sulphuric acid

Menthol (cool) and ammonia (prickling) are used to test the tactile components. The taste components are tested with chloroform (sweet) and pyridine (bitter). Bornstein uses 20 cc. glass stoppered bottles as containers for these smell substances. In testing a patient he uses the weakest solution first, each nostril being tested separately with the eyes closed. He then tests the sense of taste, using cane sugar solutions of 4, 10 and 40 per cent, a sodium chloride solution of 2, 5 and 15 per cent, a 1, 5 and 10 per cent citric acid solution and a quinine solution of 0.075 and 1 per cent.

In testing a patient's sense of smell, one must take into consideration that the sense of smell varies in different persons and in the same person at different times. This is due to a number of physical and biologic factors, i. e., the dampness of the atmosphere and the presence or absence of infection of the nasal mucous membrane.

The concentration of an odor naturally must be greater to be recognized than merely to be detected. Also, it is easier to recognize a known odor.

Having detected the presence of a hyposmia or anosmia through an olfactometric examination, it next behooves one to attempt to determine the causative factors. This may, or may not, be a difficult problem. A complete obstruction to both nares would materially point toward a respiratory disturbance. In the past, in many instances, it was impossible to prove this. The intravenous or hematogenous olfactory test of Bednar and Langfelder[6] has given a means of differentiating these two conditions. If a patient fails to perceive an odor after an intravenous injection of an odorous substance, a diagnosis of essential or psychic anosmia must be made. It was formerly thought that a psychic olfactory disturbance existed in patients in whom only a few smell qualities were missing. It is now known that this condition exists frequently in nonpsychic persons, i. e., in patients who formerly had a complete anosmia and in whom a gradual improvement of the sense of smell is taking place.

In patients with a neurosis or psychosis the results of several olfactometric examinations may vary without reason. One must observe the patient closely while making the olfactometric examination. Frequently some facial expression will reveal that he has perceived an evil smelling substance. Ammonia or menthol stimulates the trifacial, which is, of course, not involved in an anosmia. If he denies these sensations, one must be suspicious. If the patient is sufficiently intelligent to realize that these sensations are of touch, one cocainizes the nose. If he is still able to differentiate the true smell substances from those producing tactile sensations, there must be some sense of olfaction left. Every type of olfactory disturbance may be simulated in neurotic persons. Usually there are other nervous manifestations which assist in the diagnosis, i. e., hemiparesis or hemianesthesia. Another important factor in the diagnosis of a functional lesion of the olfactory apparatus is the result obtained in the Bornstein test. In functional cases there is frequently an anosmia with a loss of tactile sensation in the nose, of nasal taste and of gustatory taste sensation. A lesion sufficient to cause these symptoms would include the involvement of the olfactory, trigeminus and glossopharyngeal nerves and could easily be determined clinically. It is always necessary to make several olfactometric examinations in patients suspected of being neurotic or in cases of traumatic anosmia. Finally, the psychogalvanic reflex may be of value in determining the presence of the sense of smell in these persons.

It is impossible to differentiate the peripheral and central essential anosmias except in those cases of central anosmia in which the causative lesion produces other symptoms referable to the destruction of other cerebral structures. Because of bilateral innervation, no certainty exists as to the location of the lesion, even in unilateral anosmia. It is known that in unilateral lesions of the uncus when a hyposmia or anosmia is present, rapid compensation or equalization takes place.

The reason for this paucity of knowledge is the almost total lack of accurate postmortem examinations in cases in which olfactory disturbances have been discovered during life. Every rhinologist should attempt to procure a thorough postmortem examination in his olfactory cases. This work should be carried out only by someone especially versed in olfactory anatomy.

Disturbances of smell help to localize the site of the lesion following injuries to the skull. Frequently, olfactory disturbances are the only symptoms noticed by patients who have a traumatic skull injury. Whereas most surgeons who come in contact with a large number of skull fractures give but little or no attention to the olfactory disturbances suffered by these patients, they could be of great service to rhinologists if they could be induced to investigate this phase of the subject.

Olfactory Disturbances from a Forensic Standpoint.—It is rather a difficult question to determine the financial loss sustained by a patient in whom the sense of smell has been destroyed. Little information on this subject exists either in textbooks or in books on forensic medicine. Many people employed as butchers, bakers, cooks, brewers, wine, coffee and tea tasters, gardeners and perfumer's chemists suffer a great loss and frequently are unable to pursue their vocations. In these people the loss sustained ranges from 5 to 40 per cent. Some authors state that it is almost impossible to estimate the disability in a given case. They recommend that after a competent rhinologist has decided that the olfactory sense has been destroyed, the amount of disability can best be estimated by a jury of men engaged in the same class of work as that of the injured person.

Anosmia and Its Effects on Taste Perceptions.—Crosland, Goodman and Hocket[7] after a very careful investigation have concluded that patients suffering with anosmia are not inferior to controls in naming foods placed in their mouths.

Prognosis.—The prognosis of respiratory olfactory disturbances is good when the causative factor can be removed. In the essential anosmias of the peripheral type, especially those of toxic origin or those that follow influenza, some improvement may be expected, but complete restitution cannot be promised. Even the traumatic cases are not hopeless, as some patients recover at least a portion of their olfactory sensation.

Treatment.—In the respiratory and in the toxic essential anosmias, removal of the causative factor is the first indication. For the essential type some authors recommend quinine, strychnine and arsenic. Others recommend the use of a high frequency current of low intensity. One author recommends the use of radium, which he thinks acts as a direct stimulant to the nerve-endings.

QUALITATIVE DISTURBANCES

Cacosmia.—This condition was formerly erroneously called subjective cacosmia. It has been shown by investigators that it is only apparently subjective and that there is really an adequate stimulation in these cases, this being the causative factor, even though in some cases this causative factor cannot be found. The odor is always disagreeable, is due to the decomposition of tissue, such as pus cells, and is usually noticed by the patient on expiration. Its usual sources are tonsil plugs, carious teeth, sinus empyemas, gastric disturbances, obstipation, bronchiectasis and other pulmonary conditions and degenerating syphilitic ulcers in the respiratory tract. Specht [8] referred to a patient who experienced a bad odor which disappeared when an osteomyelitis of the forearm was drained. The causative factor may be difficult to find, owing to the many hidden recesses in the upper respiratory tract.

Parosmia.—Some authors classify as parosmia only those disturbances of smell in which there is a perversion in the perception of smell qualities. Many of the modern investigators of this condition add to the parosmias those cases in which there is a perversion of individual odors, the so-called stable hallucinations. The perverted odors have a strange and usually a disagreeable quality. Parosmia may be of peripheral or central origin and is caused by a lesion in the olfactory sense organ or in the olfactory perceptive nervous system. The presence or absence of a change in the feeling tone for an odor has no significance as far as parosmia is concerned. Parosmia is a condition of considerable importance and may rob a patient of many of the pleasures of life. In some persons it causes malnutrition; in fact, the entire psyche may become unbalanced. Food, clothing, friends and everything with which the patients come in contact may have a vile odor, making life almost unbearable.

Influenza, especially when associated with sinus infections, is the most common etiologic condition in the peripheral type. Parosmia has been caused by the local application of silver nitrate, alcohol and cocaine to the olfactory mucous membrane.

Cases of Peripheral Type: Mackenzie [9] reported the case of a physician to whom violets had the odor of phosphorus; Beyer,[10] a case following influenza in which the patient confused xylene with benzoin and to whom asphalt had a nauseating odor. Cloquet's [11] patient could not perceive vanillin, but was very fond of peruvian heliotrope, which has an odor similar to vanillin. Cloquet also referred to Grundell's case of a priest to whom all odors resembled cabbage or manure.

In the more modern literature, Rollette,[12] who developed a parosmia following the application of alcohol to his olfactory mucous membrane, described his own experiences. These should be read from the original paper. The most important contribution to the literature of parosmia is that of Hofmann.[13] Following an attack of influenza, Hofmann developed an anosmia, complicated by a parosmia. He described in minute detail the result of his experiences with this condition. At first, he could not perceive odors of any kind; gradually some odors became perceptible, after a time the latter were more easily perceived and finally he was able to smell them in their normal intensity. In the beginning these odors were not characteristic of anything that he had ever smelled, but had a woolly, alcoholic or repulsive odor. He stated that he lived in a world of unknown smells. Knowing in advance the name of an odor with which he was about to test himself seemed only to make him more aware how strange the odor he perceived really was. In parosmia, generally speaking, the normal impression of an odor returns in proportion to the increase in the intensity of the odor. All odors do not return at the same time or degree. Patients may never completely recover their sense of smell, or it may take months or years for them to regain it.

Cases of Central Parosmia: The following cases are examples of parosmias which developed subsequent to the use of certain drugs. After taking antipyrine, one patient noticed an odor of cinnamon. Santonin produced a burned odor which lasted for three days in another person; arsphenamine, an odor of roasting coffee in another. All of these were of a temporary nature.

The parosmias of pregnancy quite likely result from the toxemia of this condition. The parosmias that occur during the climacteric period are very likely of the same nature. Robertson [14] reported a case of parosmia which followed a traumatic iritis and choroiditis; he thought it due to an irritation of the olfactory tract.

Parosmia occurs in beginning tabes and in senile anosmia; here the lesion may be found in the olfactory bulb. It may also occur in diseases of the olfactory tract, the gyrus occipitotemporalis and the gyrus hippocampus. Several cases have been reported which followed injuries of the head. Cerebral hemorrhage is also a causative factor.

In a 50 year old patient with marked arteriosclerotic changes, all olfactory stimuli produced the odor of heliotrope.

Lockmann's patient [15] had perversions of smell which were caused by destruction of the olfactory tract by a carcinoma. Cullerier and Maignault[16] reported the case of a patient who complained of a constant bad odor, the causative factor being an ossification of the arachnoid membrane.

Treatment.—The older books recommend either a stimulating tonic containing strychnine and arsenic, or the bromides or iodides. Sternberg[17] has successfully treated a number of patients suffering with the peripheral type of parosmia by intravenous injections of an odorous substance. Most of his patients were cured after one or more injections; in others the condition was improved.

Smell Agnosia.—A smell agnosia exists when a patient is able to perceive a given odor, but is unable to recognize it, even though it may be of the most common type and an odor with which at one time he was well acquainted. These persons who are unable to recognize certain odors usually state, "Yes, that is it," when told the name of the odor. Henschen[18] made a thorough study of this condition by making a complete investigation of the nineteen cases seen in his own practice, and also of those cases which had been reported in the literature. His conclusions were in accord with those of Ramon y Cajal and Bechterew, i. e., that agnosias resulted from lesions of the secondary smell centers. In one of Henschen's cases there was an abscess in the second and third temporal convolutions. In another case there was considerable destruction of the gyrus hippocampus. The uncus and portions of the cornu ammonis were not destroyed.

Hallucinations.—Hallucinations of smell are another form of olfactory disturbances. Whereas parosmia is caused by a lesion of the bulb or the olfactory perceptive system, hallucinations and agnosias are supposed to originate in the secondary olfactory centers and especially in the cornu ammonis. Like the parosmias, they are produced without objective stimulation. They are therefore frequently found as a symptom of tumor of the brain, in epilepsy and in the insane. The odorous hallucinations are usually unpleasant, resembling decaying proteins, something burning, or an apothecary shop. Those occurring as a result of the acute intoxications and in hysteria may be of a pleasant nature. Marcus[19] stated that until 1909 only four cases of epilepsy with hallucinations of smell in which complete postmortem examinations had been made were to be found in the literature. The pathologic changes in these cases had a common localization, the lesion being in the region of the cornu ammonis or the hippocampus region of the temporal lobe. Since 1909 many more have been added to this list. There are a number of cases reported in which the patients have suffered with epilepsy and in which extensive lesions of the cornu ammonis were found, but no hallucinations of smell occurred. On the other hand in all cases of epilepsy with smell aura, the cornu ammonis was found involved; whereas, in tumors elsewhere in the brain, no such hallucinations were observed. According to Jelliffe,[20] certain tumors lying on the orbital plate of the sphenoid and compressing the olfactory lobe have seemed to give rise to unilateral or bilateral hallucinations of smell. In certain psychogenic epilepsies the olfactory symbolisms are highly determined; what relationship these have, either as a cause or as a result, to the lesions of the cornu ammonis found in these epileptics has not been determined.

There is not always an objective disturbance of smell in these cases, even when a destructive lesion of the cornu ammonis exists. This is due to the fact that the cornu ammonis is an association center. The primary olfactory center is supposed to be located in the uncus. It is also true that a unilateral lesion of the uncus, or even of the uncus, gyrus hippocampus and cornu ammonis, may not produce a loss of the sense of smell, because of the bilateral innervation of the sense of olfaction. When a loss is present, compensation usually results. There have also been quite a number of hallucinations of smell reported following injury to the brain. Akutzinsky[21] reported a case of epilepsy with olfactory hallucinations associated with an objective disturbance of smell, in which on postmortem examination, a bullet was found in the anterior pole of the gyrus hippocampus and the turning point of the uncus. Hallucinations of smell are frequently observed in mental cases, in the hysterical, or even in persons who are under a severe psychic strain. Specht[8] reported the case of an excited woman who smelled compound solution of cresol on her sick child's breath. A woman in the same neighborhood also smelled the odor. The most minute postmortem examination failed to reveal any compound solution of cresol, the child having died of pneumonia.

Hallucinations of smell and taste are often observed in mental cases, and patients frequently refuse nourishment because of their presence.

A physician must always feel skeptical of patients complaining of hallucinations of smell. The possibility of the presence of any odors must be carefully excluded, especially if the patient has been confined in a hospital where odors may be carried by the hands, hair and clothing. It must be remembered that most of these patients are ill, many with mental disturbances, a condition which makes their observations uncertain. Something may call the attention of these people to the odor of their mouths or bodies, and smells may thus be perceived which were previously unnoticed.

Differential Diagnosis.—When hallucinations occur in mentally sound patients, it is sometimes practically impossible to determine whether one is dealing with an hallucination, a cacosmia, a parosmia, an illusion, a cosensation or synesthesia, or an eidetic image or smell memory. In cacosmia the odor is more or less constant and the causative factor can usually be found in the respiratory tract.

The parosmias are probably to be differentiated from the hallucinations in that the latter are due to irritations in the secondary association centers. The parosmias, in contradistinction, are due to a lesion in the perceptive portion of the olfactory system. Clinically, they can be differentiated only in that the hallucinations come periodically, whereas the parosmias are prolonged over a greater period.

Illusions.—It may be stated that an illusion of smell occurs when an objective stimulation is present which, however, does not produce a normal perception on account of an active psychic imagination producing a false perception. This perception is usually based on a previous experience.

Carpenter[22] described a case in which a sexton distinctly smelled the odor of decaying flesh while exhuming a body, only to find the coffin empty. In a second case a chemist, after smelling denatured alcohol, again smelled the pyridine base odor with which it was denatured, when he was asked to smell a quantity of pure grain alcohol.

An illusion varies from an hallucination in that the odor perceived is not stable, and if careful inquiry is made, the basis for the illusion can usually be determined.

Synesthesia.—It is a well known fact that in some people a stimulation of one sense organ will produce a sensation from another organ; e. g., stimulation of the sense of hearing may bring about an odor. This may be illustrated by citing the case of a woman, who, on hearing a false note, noticed a bad odor. The sense of smell may also be associated in the same way, the odor of geraniums producing the visualization of a deep red color in one person; garlic, a deep green in another. These are always constant and in this they vary from the eidetic images. They vary from the hallucinations in that they are produced only by objective stimulation.

Jaensch[23] and others investigated the observations made by J. Müller, Goethe, Fechner, Urbantschitsch and others, and came to the conclusion that primitive man experienced not after-images but eidetic images, the difference being in the structure of the images. The structure of the eidetic image is an exact replica of the original, both in plastic form and color, the "I" being on the same plane as the image. These investigators also stated that children between the ages of 6 and 12 have no after-images. With abstract education, or training by the science of words, plus the influence of puberty, a cleavage of the primitive (Einheit's *Form*) results in a transformation of the eidetic images into after-images. This change occurs only in the higher senses. A few people retain the eidetic images even in the higher senses throughout life.

In olfaction and in the sense of taste, eidetic pictures remain and may come to some persons immediately after perceiving an odor. In other cases minutes, hours or even weeks may intervene between the time that the odor was perceived and the image experienced. It may also arise incidentally without apparent cause. The eidetic image may be experienced in conjunction with one or more of the senses, such as sound and vision.

A careful inquiry will usually allow one to differentiate eidetic images from hallucinations.

Ziem[24] pointed out that an incorrect diagnosis of hallucinations may end disastrously. He cited two cases in which patients had been committed to an asylum on account of olfactory hallucinations and had died in this institution. Postmortem examination showed that they both had had badly infected antrums, which were probably the cause of their odor perceptions.

A correct diagnosis of qualitative olfactory disturbances is also essential in that the cacosmias and peripheral parosmias are of a benign nature, whereas the central parosmias and hallucinations usually signify cerebral disease.

The entire subject is complicated, and the borderline between these different conditions overlaps and at times it becomes impossible to differentiate them.

SUMMARY

1. In patients with olfactory disturbances it is advisable to make tests of the acuity of the sense of smell, nasal taste, nasal tactile sense and the gustatory sense.

2. Careful olfactometric examinations followed, when possible, by accurate postmortem examinations will extend the knowledge of olfaction. The cooperation of surgeons who come in contact with numerous skull fractures should be sought to assist in this problem.

3. The intravenous injection of smell substances appear to be valuable in: (*a*) differentiation between the respiratory and the essential anosmias, and (*b*) the treatment of the peripheral parosmias.

4. Since the cacosmias and the peripheral parosmias are of a benign nature, it is essential that great care be taken in differentiating them from the central parosmias and hallucinations which point toward some serious cerebral disturbance.

ABSTRACT OF DISCUSSION

Dr. Claude L. La Rue, Shreveport, La.: Relatively few patients come to me primarily because of impaired or absent sense of smell. By far the greatest number have infectious diseases, sinusitis, chronic rhinitis or influenza, and seek relief from these conditions, mentioning incidentally the olfactory disturbance. Usually the sense of smell satisfactorily returns as they are cured of the infection. Some have nasal deformity following trauma, so that air cannot enter the respiratory clefts, while the smallest group comprises those with anosmia of central origin—intracranial inflammation, new growths, basal fractures. In these days of compensation insurance, one must not too quickly conclude that a trauma to the nose preceding impaired olfaction is necessarily its cause; neither must one take too seriously the patient who blames a previous nasal or sinus operation for his inability to smell, because usually the disease for which the operation was performed, not the operation itself, is the cause. From the standpoint of localizing intracranial pathologic changes, or even determining their presence, our present tests for olfactory dysfunction are not of great value, being vastly overshadowed by other more important means. From the rhinologist's standpoint, knowledge of the olfactory system and ability to diagnose its lesions at least does much toward restoring a considerable degree of satisfaction and pleasure to those having olfactory dysfunction. Better olfactometric examination on the part of the rhinologist, as advocated by the author, is certainly warranted.

Dr. George B. Collier, New Orleans: The olfactory region of the nasal cavity comprises the superior nasal concha and the corresponding part of the septum. The olfactory fibers arise by bipolar cells, form a plexus beneath the mucous membrane and ascend in grooves in the ethmoid bone, passing into the skull by way of the cribriform plate and entering the olfactory bulb, thence to the olfactory area in the brain. These areas, while not as easily localized as the eighth and optic nerve, have not been used as much in the past as they should be by industrial surgeons and others doing surgery of the head and making diagnosis of lesions. Nevertheless, with the better trained brain surgeons and the more scientific rhinologists working in cooperation and spurred on by such papers as Dr. Seydell's, there is no reason why this nerve tract should not be used more and greater importance attached to it, especially in localizing brain tumors and injuries. Gunshot wounds or other penetrating wounds that would sever the bulb would cause complete loss, and any abnormality preventing access of air to the olfactory area will decrease the sense of smell, as septal deflection, hypertrophy of the turbinates, common head *colds, and inflammatory diseases. In influenza and other spe-*

cific diseases the anosmia may be partially due to a direct toxin. Accessory-sinus disease bears a definite relation to smell and quite often is an important symptom. The more one finds in the way of nasal obstruction, the better the chance for recovery. Attention to diseased sinuses gives improvement. In atrophic rhinitis with injury to the nerve endings, little can be expected. The toxic type, if not of too long duration, will improve if the cause is removed.

Dr. William D. Gill, San Antonio, Texas: In my experience, functional testing of the sense of smell has had its greatest field of usefulness in examination of patients with mental disorders, especially early dementia praecox, as such patients will often admit having an hallucination of smell when other types of hallucination are denied. I have seen the practical application of these tests in the examination of recruits for military service, and they are also of value in the examination of prospective employees in the industrial field, as they frequently protect against employees with incipient mental disorders and often forestall insurance claims in malingerers complaining of the loss of smell. The latter point is especially important in chemical industries. Another point that may be mentioned is that examination of a patient with a suspected brain lesions, such as tumor or abscess, is not complete until the sense of smell has been tested qualitatively. Lesions of the base of the brain in the frontal and prefrontal regions, and of the uncinate gyrus, are the locations in which lesions most frequently produce disturbance of smell. In cerebral localization other substantiating neurologic tests should be employed, such as estimation of the visual fields. Little information can be gained by testing the olfactory sense in acute brain injuries, the reason being that the critical condition of most of these patients precludes their cooperating with the examiner. Sharpe's book on brain injuries has nothing in the index regarding disorders of olfaction in acute brain injury. To the neuropsychiatrist functional testing of the sense of smell has its greatest practical application, but to the otolaryngologist such tests are equally important and demand just as serious consideration. It may be well to sound a warning note at this point against destructive nasal surgery, as many of the patients subjected to radical operation complain of loss of smell after such procedures. Profit can be gained by paying serious attention to the principles of ethmoidal surgery as outlined by Pratt of Minneapolis. Much of the joy of living is lost by patients who are deprived of the sense of smell by too radical intranasal surgery, as the impairment or loss of the sense of smell and sense of taste makes such patients quite unhappy.

Dr. Ernest M. Seydell, Wichita, Kan.: There can be no progress in olfaction until rhinologists make olfactometric examinations on patients suffering with olfactory disturbances and report those cases which present instructive factors.

Primary Lesion in Hepatic Cirrhosis.—I believe that the primary lesion in cirrhosis is one which depends on slow progression but frequent repetition. It consists, first, in degeneration or destruction of liver cells, followed by regeneration and replacement by new liver cells, but with some overgrowth of fibrous tissue in the areas which are destroyed. The essence of this view is the conception that the damage in the liver is one which is focal, but frequently repeated. Areas of liver cells die, and are replaced by new areas built up from surviving cells; these new areas are again destroyed, and again rebuilt, but increase of fibrous tissue gradually supervenes as the process of death and repair is repeatedly carried out. Finally, on this view, an entirely new liver parenchyma, containing perhaps not a trace of the old and original liver, is built up on a plan which has the appearance we describe as cirrhosis. Not only has the entire parenchyma been repeatedly destroyed and renewed, but, as is well known from the work of many pathologists, new bile ducts are made and joined up in functional relation with the new glandular cells. Even the blood vessels and their branches—both of the hepatic artery and of the portal vein—are involved and the whole circulatory plan in the liver is markedly altered.—McNee, J. W.: Croonian Lectures on Liver and Spleen: Their Clinical and Pathological Associations, *Brit. M. J.* **1**:1111 (June 18) 1932.

A CONTRIBUTION TO THE STUDY OF SO-CALLED LIVER DEATH

CARL BRYANT SCHUTZ, M.D.
FERDINAND C. HELWIG, M.D.
AND
HAROLD P. KUHN, M.D.
KANSAS CITY, MO.

So-called liver death has been the subject of considerable discussion in recent publications, and numerous observations have been made regarding the clinical course and possible etiology of these unfortunate disasters, which all too frequently follow surgical procedures on the gallbladder and bile tract.

In a recent study of several postoperative deaths in patients suffering from gallbladder disease and coincident hepatic damage of long standing, we[1] were struck by a peculiar and constant chain of symptoms and necropsy observations which suggested a pathogenesis for this rather obscure type of liver death.

The first case we[2] observed was one of traumatic pulpification of the liver in a boy, aged 16 years, who died eleven days after an accident. The most striking clinical manifestations were oliguria (which progressed to anuria) and uremia associated with hemorrhages from all mucous surfaces. The symptoms were accompanied by a marked retention of blood nitrogen. At necropsy the most striking finding, aside from the pulpified liver, was a high grade nephrosis. After considerable study of this case, we assumed that the nephrosis was produced by some toxic product elaborated by the pulpified liver which had some specific deleterious effect on the kidneys. Subsequently we observed four patients who died following cholecystectomy in whom the clinical course was similar to that of the patient who died following the liver trauma. In another instance we studied a patient who died in a state of coma with clinical manifestations closely paralleling those seen in the foregoing five cases. The latter patient was a woman, aged 39, who had a diffuse metastatic carcinoma of the liver secondary to a carcinoma of the breast (removed eleven weeks previously). Necropsy revealed marked degenerative lesions in both kidneys.

In none of these patients could any infection be demonstrated, and all showed marked changes in both the liver and the kidneys.

THE HEPATORENAL SYNDROME

The clinical and necropsy observations were unusually interesting and fairly constant. With the exception of the first and last case mentioned, all gave a history of long standing gallbladder disease. In all cases, careful preoperative blood and urine studies presented normal conditions. On about the fifth or the sixth postoperative day the patients developed a rise in temperature and pulse rate, accompanied by abdominal distention and a progressive oliguria with the appearance of albumin, casts and often red cells in the urine. With the increase in oliguria, the patients lapsed into delirium and then coma, the nitrogenous elements of the blood increased progressively and the urinary nitrogen became greatly diminished. Nausea and vomiting were

often severe, and mucous surface bleeding frequently became a prominent feature in the clinical picture. In the latter part of the illness, blood often in large amounts was found in the stools and the vomitus. The clinical picture then progressed to that of uremia with generalized low grade edema and almost total anuria. The blood nitrogenous elements continued to increase and the patients died in a state clinically resembling uremia.

The conditions found at necropsy were relatively uniform. Low grade generalized edema was almost always present and the operative wounds showed little or no healing. The gastro-intestinal tract contained blood in large amounts, which apparently originated from submucous hemorrhages. Not infrequently hemorrhages were found in the mucous membranes of the mouth, respiratory tract and kidney pelves. The liver and kidneys were always the seat of striking degenerative changes. In the former, either leukocytic infiltrations, necrosis and interstitial hemorrhages, or marked parenchymatous and fatty changes were present. The most advanced lesions were seen in the liver tissue about the gallbladder fossa in these operative cases. The kidneys always presented a marked nephrosis. Parenchymatous swelling and loss of normal markings were the outstanding gross observations, while, microscopically, tubular epithelial degeneration progressing to actual necrosis was almost constantly observed. Patchy focal hemorrhages and areas of leukocytic infiltration were the rule, while the glomerular changes were not noteworthy.

CLASSIFICATION

In a large series of so-called liver deaths recently analyzed by Heyd,[3] wherein the death could not be ascribed to the usual types of mortality, he has classified the deaths into three groups, as follows:

Group 1. "Hepatic exhaustion," which he thinks is due possibly to decreased chemical activity of the liver resulting in an alkalosis which causes death. The mechanism of this condition is still quite obscure.

Group 2. The jaundiced patient who has had a rather satisfactory postoperative course for a few days when a distinct change in the character of the bile drainage occurs; it becomes thin, watery and decreased in amount. The patient becomes delirious, lapses into coma, and dies. In these instances, Heyd thinks that the sudden release of the obstruction (the majority are common duct operations) may result in an acute secondary hyperemia of the liver with resultant failure of liver function.

Group 3. The nonjaundiced patient with pancreatitis and common duct disease who, following a drainage of the common duct, does well for twenty-four hours and then goes into a state of shock with cessation of urinary secretion. This is brought about, he thinks, as a result of overwhelming intoxication of pancreatic origin.

Unfortunately, no necropsy studies were recorded and very few substantial facts relating to the actual mechanism of these clinical manifestations are brought forward to account for them. Therefore, we wish either to amend certain phases of this classification or at least to contribute some additional data to the study of this distressing problem.

In our cases only two showed any evidence of jaundice, and in one of these it was very faint. In neither instance did we consider the jaundice of any importance in the causation of the kidney damage, as no obstructive lesions were present and the kidneys did not show the microscopic picture of bile nephrosis. The jaundiced patient presents a characteristic train of symptoms, which have been well summed up by Walters[4] and again by Heyd. This type of case is referred to in group 2 by Heyd in the foregoing discussion. In groups 1 and 3 in his series there was no jaundice and in group 3 he considered the condition due to pancreatitis resulting from common duct obstruction and he felt that some toxin was elaborated by the diseased pancreas which caused the clinical syndrome he has outlined. Therefore, we feel that group 1 of Heyd's series, which he ascribes to "hepatic exhaustion," would more nearly compare to the cases we have observed.

COMMENT

In all instances in which gallbladder disease was the reason for surgical intervention, we obtained a history of long standing cholecystitis and, at both the operation and the necropsy, liver damage of considerable duration was encountered. We feel that the deaths which ensued in these individuals were not the result of cessation of liver function since there was apparently no impairment in glycogenesis, as evidenced by blood sugar determinations, nor was there any evidence of failure to deamidize the amino-acids, since urea formation was unhampered and progressive increase in the nitrogenous products in the blood was found in every case. In all of our patients, the stools contained bile, and no other evidence of any lack of hepatic function was found. Unfortunately, we did not carry out any tests for impairment of fibrogen production.

MECHANISM

The mechanism responsible for the kidney damage is, of course, obscure. All our patients died in a state clinically resembling uremia and in not a single instance was there any evidence of previous kidney damage. Therefore, we concluded that the damage to the kidney must have been brought about by some toxin elaborated by the diseased liver which acted more or less specifically on the kidneys. It will be observed in the summary of the necropsy observations that none of the other parenchymatous organs showed any evidence of profound alteration such as was encountered in the kidneys. Hemorrhages were almost always present and they were seen most frequently in the gastro-intestinal tract, although they were not infrequently encountered elsewhere. Similar hemorrhages have also been observed by LeNoir[5] after operation for gastric ulcer. The patients in his series vomited large quantities of blood, and at necropsy the gastric ulcer was shriveled and no eroded vessel was seen. However, a severe hepatonephritis was uniformly present and the patients died in a state of uremia. The liver and kidneys both showed marked damage. Walters and Parham[6] have observed uremia and gastro-intestinal hemorrhages in patients who died following operation for obstructive jaundice, and Zaffagnini[7] saw hematuria in patients with gallstones. Hemorrhages from the gums was seen by Thiers[8] in a fatal case of apiol poisoning with uremia and severe liver damage, while Gundermann[9] experimentally produced uremia with blood in the urine and the gastro-intestinal tract by ligation of the hepatic artery. This procedure produced atrophy and degeneration of the liver. Moreover, by injecting liver cells intravenously he was able to produce a hemorrhagic diathesis with bleeding into the gastro-intestinal tract.

[8] Thiers, H.: Fatal Hepatonephritis, Compt. rend. Soc. de biol. **106:** 303-304 (Feb. 6) 1931.

The explanations that have been advanced for the hemorrhagic phenomena have been ascribed to either impairment in fibrinogen formation or increase in bile salts in the blood. However, in the absence of jaundice and with no other evidence of impaired liver function in our cases, we feel sure that these two factors are highly speculative and relatively unimportant if not incorrect. Recently, White and Jankelson[10] noted severe hemorrhage from the gastro-intestinal tract in a group of cases of gallbladder disease in which jaundice was an unimportant factor, and they considered that a hepatitis associated with the diseased gallbladder elaborated a toxin into the blood which caused surface bleeding of the gastro-intestinal mucus.

Experimental studies have been carried out in animals by two of us[1] in an attempt to produce a secondary kidney injury. Through mechanical trauma to the liver, as well as by ligation of the hepatic artery, we induced hemorrhagic necrosis in the livers of dogs and rabbits, which was soon followed by degenerative changes in the kidneys. A striking rise in the nitrogenous products of the blood was seen, while a marked oliguria resulted, and the urine contained red cells, albumin and casts. If the animals were killed while the blood and urinary changes were most striking, lesions similar to those seen in our patients were observed. These experiments likewise suggested an elaboration of some toxin from the liver which acted more or less specifically on the kidneys.

TREATMENT

A careful analysis of these cases of liver death suggest that the primary factor in the syndrome is due to a diseased liver. In this type of death which we are reporting, the kidney damage resulting in uremia is probably brought on by toxic products elaborated in the liver, acting secondarily on the kidney. Unfortunately, it is difficult if not impossible to estimate the degree of liver damage which is present prior to operation, since it is rather definitely demonstrated that the liver function, so far as its physiologic activity is concerned, is not disturbed. Maintenance of sugar level, deaminization and bile production are all unaltered. And our experiences with function tests, which crudely estimate the ability of the liver as an excretory organ, have not been particularly promising. However, recently Graham[11] and Cole, by the use of iso-iodeikon (phentetiothalein sodium-N. N. R.) in doses of 2.5 Gm. to the average adult, have obtained such encouraging results that now they refuse to operate on patients with a high dye retention. It has been our rule since studying these cases in our series to supply the liver with glycogen by large amounts of sugar preoperatively which can be given by mouth or intravenously, since it has been shown by Bollman[12] that the detoxifying action of the liver is greatly increased when the hepatic parenchymatous cells have a generous glycogen storage.

Dr. Frank Mann[13] of the Mayo Clinic suggested the possibility that suturing of the liver around the hepatic fossa might cause sufficient hemorrhage and death of liver cells to produce toxic products, and this assumption seems quite reasonable in view of the fact that the most profound changes of both an acute and a chronic nature were found in the liver parenchyma in this region. Furthermore, the necropsies strongly suggest that dead liver tissue may be one of the possible sources of the toxin, since in our cases intrahepatic hemorrhages with necrotic liver cell foci were so often found. Hence, it might be inadvisable to suture the liver after cholecystectomy.

In dogs, Lamson, Minot and Robbins[14] observed a marked acceleration in hepatic repair after poisoning with carbon tetrachloride when the animals were given small amounts of calcium chloride, and Graham[11] has instituted the use of calciums in his postoperative gallbladder cases with happy results. After so-called hepatic coma has set in, the treatment is very difficult. Snell[15] mentions that in Morawitz's clinic lactic acid is used intravenously and this alone or in combination with dextrose apparently produces temporary improvement in hepatic function in these terminal states.

SUMMARY

From the foregoing observations, we feel that there is a definite type of so-called liver death which is due to some toxin elaborated in a diseased liver, which toxin acts directly on the kidneys, producing a profound degenerative change in those organs. We have observed a certain fairly definite clinical and pathologic syndrome which was seen in one case of traumatic liver pulpification, one of diffuse carcinomatous metastases in the liver, and four of long standing cholecystitis with a concomitant high grade hepatitis. All these patients died in a clinical state resembling uremia, and all showed extensive degenerative lesions in the kidneys. The blood and urinary studies were substantiated by the changes found in the kidneys. Hemorrhages from the mucous surfaces were present in four cases and their origin has not been explained.

This type of death resembles more closely the so-called hepatic exhaustion as outlined by Heyd[3] and should be differentiated from the deaths occurring after operation on the bile ducts when the patient is jaundiced, since jaundice was present in only one case in our series and even in this instance no change in the character of the bile drainage was ever observed.

CONCLUSIONS

The clinical behavior in this group of cases and their similarity at necropsy have led us to assume that liver damage, whether traumatic or infectious in origin, produces a selective toxin which may severely damage the kidneys.

In view of the fact that this syndrome has always followed damage to the liver and has occurred in individuals with previously normal kidneys (as regards known tests for kidney function), we believe that the pathologic changes in the kidney are secondary to the changes in the liver. Since jaundice is not a feature of the syndrome and since liver function is not, so far as we can determine, notably decreased, we believe that often severe, and mucous surface bleeding frequently became a prominent feature in the clinical picture In the latter part of the illness, blood often in large amounts was found in the stools and the vomitus The clinical picture then progressed to that of uremia with generalized low grade edema and almost total anuria The blood nitrogenous elements continued to increase and the patients died in a state clinically resembling uremia

This type of death resembles more closely the so-called hepatic exhaustion as outlined by Heyd[3] and should be differentiated from the deaths occurring after operation on the bile ducts when the patient is jaundiced, since jaundice was present in only one case in our series and even in this instance no change in the character of the bile drainage was ever observed.

CONCLUSIONS

The clinical behavior in this group of cases and their similarity at necropsy have led us to assume that liver damage, whether traumatic or infectious in origin, produces a selective toxin which may severely damage the kidneys.

In view of the fact that this syndrome has always followed damage to the liver and has occurred in individuals with previously normal kidneys (as regards known tests for kidney function), we believe that the pathologic changes in the kidney are secondary to the changes in the liver. Since jaundice is not a feature of the syndrome and since liver function is not, so far as we can determine, notably decreased, we believe that the toxin has its origin in a by-product of liver cell destruction.

There can be little doubt that the clinical manifestations represent a definite syndrome of particular importance in gallbladder surgery. The problem of its etiology and the exact nature of its toxin requires a continuation of the experimental studies which two of us (C. B. S. and F. C. H.) are conducting.

Until more definite information regarding its etiology is obtained, the treatment of this condition must necessarily be empirical. It seems certain that the syndrome is most frequently the result of surgical delay. It therefore follows that the most important part of the treatment, for the purpose of preventing its occurrence, is preoperative. Its recognition tends to substantiate the growing surgical opinion that definite cholecystitis should not be subject to prolonged medical treatment. Preoperative liver function tests may be valuable in determining the degree of liver damage.

The use of dextrose both preoperatively and postoperatively has been the most successful form of direct treatment in our experience. The use of calcium postoperatively, as suggested by Graham, may be of value.

HYPERTHYROIDISM IN CHILDREN

A REVIEW OF FIFTY-SEVEN CASES

R. S. DINSMORE, M.D.
CLEVELAND

During the past few years, my associates and I have seen at the Cleveland Clinic a number of cases of hyperthyroidism in children. Although formerly it was thought that hyperthyroidism in children under 14 years of age occurred but rarely, our experience has led us to believe that this disease is not as uncommon as is generally supposed.

It is not within the province of this paper to review the various theories and hypotheses regarding the etiology of hyperthyroidism that have been presented, nor to review the bibliography that was so adequately covered by Helmholz[1] at the meeting of this association at Dallas, Texas, in 1926.

Means,[2] however, has discussed the two most prevalent views of Marine and of Plummer adequately and briefly, and has made the following pertinent statement: "It is evident that no one knows the primary cause of hyperthyroidism although there are those who believe that the thyroid is guilty of any one of the following disorders, or of both of the latter two: hypofunction, dysfunction and hyperfunction." In studying a group of children, however, it is especially interesting to consider the possible contributing factors in the production of the disease.

In reviewing the histories of a group of children, the possibility that there has been an hereditary factor occasionally presents itself. Dr. Crile operated on one such patient with marked hyperthyroidism, a child aged 14, on whose mother and maternal grandmother he had also operated for the same disease. I once operated on a Jewish boy of 14 who showed all the typical signs of hyperthyroidism. This lad had a brother two years younger in whom hyperthyroidism developed at exactly the same age. In three other cases, the mothers of children with hyperthyroidism had had the disease, and in one case, that of a boy, the father also had hyperthyroidism and was operated on later. In one case a mother's brother and in another the sister of the mother had hyperthyroidism.

The so-called constitutional factor is probably not important in this group of children, because in nearly every instance the child was said to be perfectly well until the onset of the disease. In certain cases, however, the statement has been made by the parents that the child had always been of a nervous temperament.

The racial factor is about the same as in adults. In our series of cases, the majority of the children were American born, of mixed parentage. I have seen the condition in an Italian child of 8 years. Seven cases occurred in Jewish children. I have seen only one case in a Negro child and only one in which the parents were Scandinavians.

In a few of the cases, the disease followed an infection, and in the case of one child who had had scarlet fever, followed by severe pyelitis for eight months, hyperthyroidism developed with an abrupt onset and a rapidly developing clinical course. In one case, the disease followed an attack of whooping cough. In another case, the patient's parents were quite insistent that the disease followed tonsillectomy, and in still another, in a patient who had had thyroid enlargement previously, the symptoms developed after an injury to the knee.

In one very severe case of exophthalmic goiter, the child also had a spastic paraplegia from a birth hemorrhage. In only one case was there an accompanying endocrine disorder. This girl presented all the symptoms of true hyperthyroidism, together with evidence of accompanying hypopituitarism. She had a very fine, soft skin, typical hyperplasia, hypertrophy of the breasts and a tendency to be overweight.

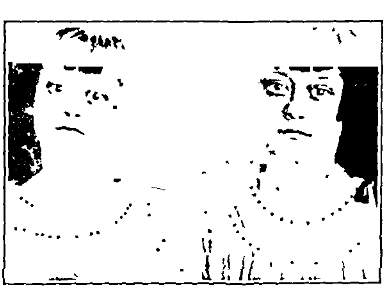

Fig 1.—The patient at the age of 9 years. The picture on the right shows her two months after thyroidectomy.

I have never been able to come to the conclusion that the administration of iodine as a preventive measure is a factor in the production of hyperthyroidism in children. Personally, I do not believe that iodine medication has either produced or lessened the incidence of the disease in children.

Geographically, our cases have come, for the most part, from the area about Cleveland, Pennsylvania and western New York, although three were from Indiana, three from Michigan and single cases from West Virginia, Illinois, Louisiana, Wisconsin and Wyoming.

Most of Helmholz's cases came from Minnesota, Iowa, Illinois and Wisconsin, the remainder coming from scattered localities in other states and in Canada.

In studying the onset of symptoms, I find that it is difficult to give absolute statistics, owing to the confused statements made by the parents.

[2] Means, J H., and Richardson, E. P: Diagnosis and Treatment of Diseases of the Thyroid, in Christian, H A., and Mackenzie, James: Oxford Medicine, London, Oxford University Press, 1920, vol. 6.

In 70 per cent of our cases, either nervousness or enlargement of the gland was the first symptom noted by the parents. The incidence of these two symptoms as the initial one is about the same, that is, 35 per cent. Often, the parent was unable to state whether the fulness of the neck or the nervousness appeared first. In seven of the cases, it was stated that the enlargement of the neck and the nervousness appeared at the same time. In only one case was exophthalmos noted as the first symptom, although in two other cases its onset was noted at the same time as that of the enlargement of the gland. In four cases, tachycardia was noted as the primary symptom, and in two, the first symptom that attracted the attention of the parents was shortness of breath on slight exertion. Loss of weight was the primary symptom in one case. In one, in which the disease followed whooping cough, the parents insisted that all the symptoms and other signs, nervousness, enlargement of the neck, exophthalmos and tachycardia, appeared at the same time.

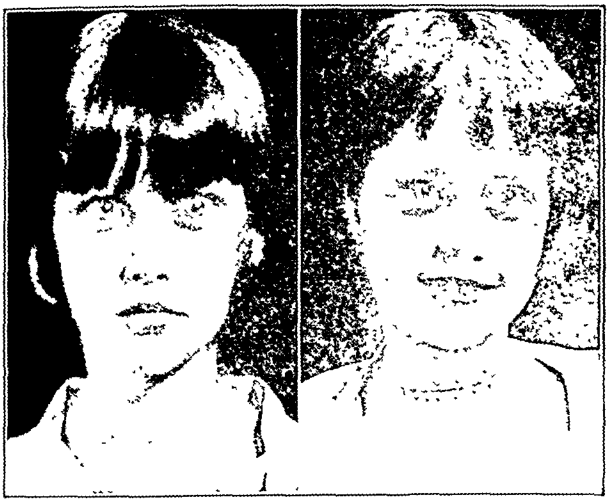

Fig. 2.—The patient at the age of 10 years. The picture on the right shows her one week after a second lobectomy.

Owing to the inaccuracies just mentioned, I am coming more and more to the belief that exact statistics concerning the sequence of symptoms will be fairly difficult to obtain. In general, however, it may be stated that enlargement of the gland and nervousness usually appear first, followed by tachycardia and exophthalmos. One child 4 years of age had had a rapid heart for a year before enlargement of the gland and exophthalmos were apparent.

The diagnosis of hyperthyroidism in a child is not difficult in most instances; as a matter of fact, these patients frequently come to us with the diagnosis already made, and in the typical case, even the casual observer can identify the disease. It is not within the scope of this paper to offer a detailed description of the typical symptoms presented by these children; among the most common symptoms are tachycardia, exophthalmos, enlargement of the thyroid gland, extreme nervousness, easy excitability, great irritability and the tendency to cry over the most trivial circumstances. In reviewing the symptoms presented by this group of patients as given in the accompanying table, I have found that they conform closely to those listed by Helmholz. A comparison of the frequency of these symptoms in our series with those of Helmholz is interesting.

Tachycardia was present in every case. The average pulse rate was 129, but varied from 100 to 180. Nervousness and enlargement of the thyroid were present in nearly every case. It is interesting to note that the incidence of bruit in our cases is much lower than that cited by Helmholz. I attribute this relative absence of bruit to the fact that most of these children had taken iodine, some of them for a fairly long time, and the gland had become involuted and very firm.

Comparison of Frequency of Symptoms in Helmholz's Cases and Those in Cases from the Cleveland Clinic

	Helmholz, 40 Cases	Cleveland Clinic, 57 Cases
Tachycardia	100%	100%
Nervousness	93%	91%
Thyroid enlargement	93%	93%
Exophthalmos	83%	76%
Bruit	70%	49%
Hyperhidrosis	67%	55%
Tremor	57%	66%
Loss of weight	53%	50%
Polyphagia	50%	40%
Weakness in quadriceps	47%	....
General weakness	....	58%
Gastro-intestinal symptoms	47%	43%
Dyspnea	40%	55%

In approximately two thirds of these cases, tremor had been a definite symptom, but the slight tremor some of the children have may be misinterpreted. Especially is this true in some of the borderline cases in which the tremor of a residual chorea must be ruled out.

In about half of the cases there had been loss of weight, in some instances amounting to as much as 20 pounds (9 Kg.). The weakness of which the patients complain is often a noticeable symptom, and in some cases myasthenia is marked. Helmholz has called especial attention to the presence of a weakness of the quadriceps femoris in these children. If a child with exophthalmic goiter is asked to step up onto a chair, he must get a start and steps up with a quick effort, while the average child steps up without effort and raises himself slowly. The other symptoms of hyperthyroidism in children are the same as in adults and need no comment.

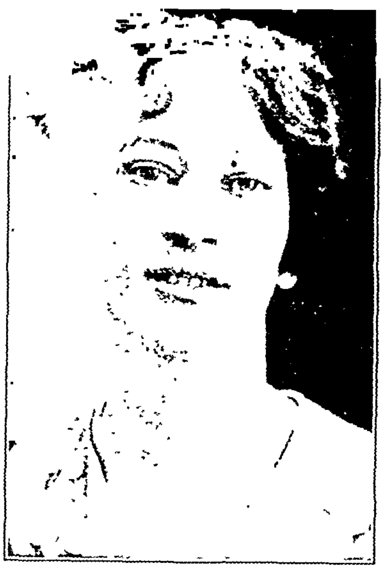

Fig. 5.—The patient at the age of 18. She was operated on at the age of 13 for exophthalmic goiter.

The symptoms may have been present from a few weeks to several years. In some cases in which the disease has persisted for a long time, it may be difficult to get an accurate history of the onset from the parents. Thus, in one instance, it was stated by the parents that all symptoms started abruptly and appeared within a fourteen day period. In 65 per cent of our cases, the disease appeared between the ages of 12 and 14 years;

in the other 35 per cent, it developed between the ages of 4 and 10 years. In one case, that of a child 4 years of age, there was a perfectly definite history that the disease had been present since the age of 2 years; the attending physician's clinical history forwarded with the patient verified this statement.

Our experience with estimations of the basal metabolism in children with hyperthyroidism has been generally unsatisfactory. In the first place, it is difficult to know that a child is in a true basal condition; secondly, there are such variations in the estimations of the basal metabolism determined by different standards that it usually appears that the standards available are not sufficiently accurate. Our tests have shown wide variation, especially from the initial reading. At the present time, we are taking repeated estimations with the patient in the hospital, by the Harris-Benedict standards for girls under 12 years of age and the Benedict-Talbot standard for boys under 14 years of age. An estimation is also made in each case by the Du Bois standards. We have not used the estimation of basal metabolism as an index for operability, and the clinical findings usually make the diagnosis obvious.

Formerly it was the practice to perform ligations in these cases and to send the child home for a period of three months, but in our latest series it has been possible to do lobectomy or thyroidectomy in practically every case. It must be remembered that for some reason the improvement that follows ligation is very definite. I have always felt that in children this improvement is greater than that seen in the average adult. Therefore, this procedure should not be discarded in favor of lobectomy if there is any doubt as to the wisdom of the latter as the primary operation.

We have now operated on forty-three patients with hyperthyroidism, with two deaths, one of which occurred before the advent of compound solution of iodine. The results of surgical intervention in this group of patients have been most gratifying, and we think that it is the method of choice for their treatment. The preparation of these patients for operation is a distinct problem and requires a great deal of time and patience on the part of the hospital staff, and especially of the anesthetist. As would be expected, the children are extremely excitable and do not take general inhalation anesthesia well. They are likely to have rather severe reactions after deep anesthesia, even though they have been carefully prepared for it, and for this reason local anesthesia and light nitrous oxide analgesia are used. The children are apprehensive, and their confidence and cooperation must be obtained. The anesthetist, who must be some one who is particularly interested in children, spends much time with each child before the operation and becomes his chum and boon companion. The child is made familiar with the anesthetic mask and is put under light inhalation anesthesia; as the result of this preparation, most of the children have behaved extremely well while the operation was being done.

Prioleau[3] has described in detail the routine that we use and has especially emphasized the fact that the child's fear of a surgical procedure in many instances is the unfortunate result of inadvertent statements about operations made in his presence by the parents.

The technical problems are the same as those encountered in adults, except that even greater care must be taken to leave enough tissue for the normal needs of a child. It must be remembered that hypothyroidism is likely to develop in these patients. A fairly marked reaction often occurs after operation; that is, all the symptoms are intensified, and it is interesting to note that often these children do not appear to be as ill as the chart would indicate. Marked tachycardia will develop along with a high temperature and flushing, but still the child does not complain, and is bright and alert and able to take fluids without difficulty. The immediate recovery from the operation is often astonishingly rapid, and when the patient is seen at the end of a few weeks, practically all of the symptoms will have disappeared.

Although these children usually leave the hospital with a small, hair-line scar that can hardly be seen, within a few weeks the scar becomes red and tender and a thick keloid develops. The incidence of keloid formation is very high in these cases. In the past three years, I have seen only one child in whom a keloid did not develop in the scar. This condition is best treated with grenz rays, which give satisfactory end-results. I think the general statement may safely be made that, the older the patient with hyperthyroidism, the better is the operative scar.

We are frequently questioned concerning the ultimate outcome of these children after operation. I have followed some of them through their high school and college days, and so far as I can tell they are perfectly normal in every respect, except that in an occasional case slight transient hypothyroidism may develop from time to time.

THE SURGICAL TREATMENT OF PROGRESSIVE EXOPHTHALMOS FOLLOWING THYROIDECTOMY

HOWARD C. NAFFZIGER, M.D.
AND
O. W. JONES, Jr., M.D.
SAN FRANCISCO

Exophthalmos as a sign of hyperplastic disease of the thyroid gland has been attributed to overactivity of certain smooth muscles in the orbit, innervated by the sympathetic nervous system, and to an increase of orbital fat. However, more attention has been given to the description of ocular signs, to which the names of some thirty or more persons are attached, than to a detailed study of exophthalmos with proof of the mechanism by which it is produced. It is rather astounding to find so little in the literature that would indicate that the orbital contents have been studied in persons dying from disorders of the thyroid gland. In view of the fact that exophthalmos is an obvious physical sign, readily apparent both to the physician and to the layman, it is surprising that nothing has been accomplished in the determination of the pathologic changes that produce it.

The result of surgical treatment for disease of the thyroid gland usually is gratifying to the patient and satisfactory to the surgeon. Occasionally so advanced a stage of the disease is reached that permanent damage already has occurred. In these patients the surgical risks are greater and restoration to health is incom-

---

Read before the Section on Surgery, General and Abdominal, at the Eighty-Third Annual Session of the American Medical Association, New Orleans, May 13, 1932.

plete. As a rule, exophthalmos recedes as other findings and physical signs abate after a thyroidectomy, but it is a matter of common observation that such regression does not follow always and that certain persons show a persistent, stationary exophthalmos. There is still a third group of patients in whom exophthalmos after thyroidectomy neither has receded nor become stationary, but actually has progressed. Though these cases are, fortunately, not very frequent, the literature, especially the ophthalmologic literature, contains many examples of this type.

The usual history of these persons is that the exophthalmos progresses until the lids no longer can cover the globes; and that, at about this time, certain other signs appear. The lids become extremely puffy, the scleral conjunctiva edematous and the movements of the globe restricted. Lacrimation and epiphora appear. A little later the conjunctival mucosa is engorged and protrudes between the lids. A stage soon is reached in which, from lack of protection, the cornea becomes dry, inflamed, ulcerated, then infected, and ophthalmitis follows. Enucleation becomes necessary, or death ensues. With the progressive exophthalmos, the limitation of movements of the eye muscles and the changes noted in the lids, there occurs, in some, a progressive blindness resulting from changes in the optic nerve. Partial or complete loss of vision may occur either from the changes in the cornea or in the optic nerve, or both.

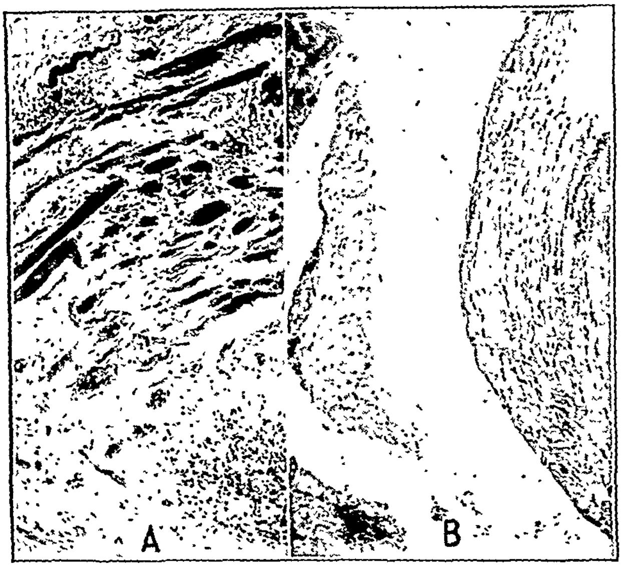

Fig. 1.—Photomicrograph of extra-ocular muscles: *B*, normal muscle; *A*, muscle taken from a patient with progressive exophthalmos, showing round cell infiltration, increased fibrous tissue, fragmentation and separation of muscle fibers.

Our attention was directed first toward the subject by a patient who presented all of these features—progressive exophthalmos after thyroidectomy, with extreme limitation of the movements of the eye muscles, swelling of the optic disks which had progressed to the stage of well advanced atrophy, and vision reduced to the recognition of gross objects at a distance of a few feet. Since that time others have been under our care, and this report presents the method of operative treatment. Incidentally, our studies have revealed the pathologic change responsible for this hitherto little understood condition. It affords a field for investigation of the factors concerned in the production of intrinsic changes in the extra-ocular muscles and in the optic nerve as well. Here it may suffice to say that progressive exophthalmos following thyroidectomy is of mechanical origin and is the result of a pronounced swelling of the extra-ocular muscles. Grossly, the muscles are from three to eight times their normal size. Microscopic study shows edema, round cell infiltration—often in a perivascular pattern—loss of muscle architecture, increase of fibrous tissue with areas of hyalinization, and fragmentation and destruction of muscle fibers (fig. 1).

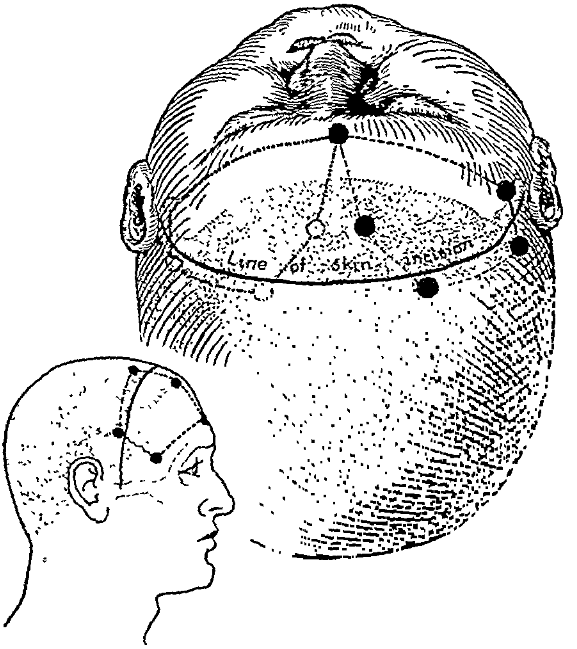

Fig. 2.—Incisions used. The solid black line indicates the coronal incision; the dotted lines, the two osteoplastic flaps.

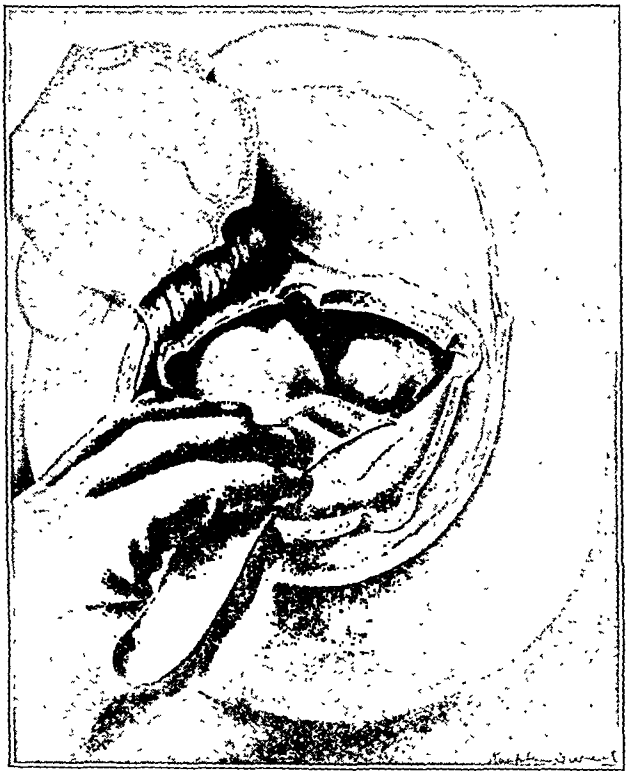

Fig. 3.—Intracranial approach to the orbit. Part of the orbital plate is removed, exposing the fascia of the orbit.

The operative treatment here outlined is not intended as a cosmetic operation, nor is it advised for those persons who have simply a persistent, stationary exophthalmos following thyroidectomy. This procedure is for those who have a progressive exophthalmos, usually with limitation of movements of the globe of the eye, with or without changes in the optic nerves and in vision. It may be pointed out here that, in certain instances, vision fails even though the cornea is clear, and the ophthalmoscopic examination reveals a normal fundus.

The principle of the operation is that of decompression of the orbit and the optic foramen in order to give adequate space for the increased orbital content and the constricted optic nerve. One well may ask at this stage, "Is such a procedure sufficient to halt the pathologic process that is occurring?" We only can answer that, up to date, it has seemed to be entirely adequate; in our patients there has been no recurrence, in all of them vision has been restored and there has been recession of the exophthalmos.

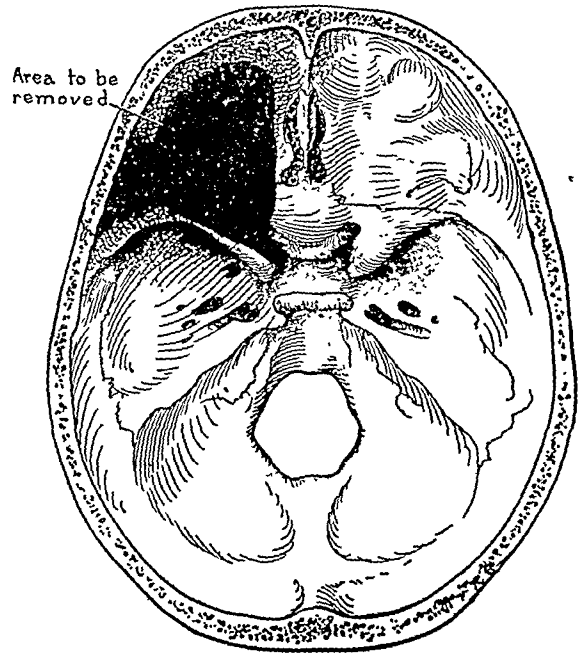

Fig. 4 —The base of the skull, showing the area of bone removed from the orbital plate and from the optic canal.

TECHNIC

The surgical procedure consists of reflecting bilateral frontal flaps, elevating the dura of the frontal lobe, unroofing the orbit and removing the upper portion of the optic foramen. The orbital fascia and the ring of Zinn are opened widely. As a preliminary to operation, roentgen studies are made to inform us of the height and extent of the frontal sinuses and the projection of the ethmoid and frontal sinuses into the orbital plate. Views of the optic foramina reveal the immediate relationship of the sphenoid sinus to it so that the operation may be conducted in such a way as not to open these cells.

The anesthetic is a matter of choice for the individual surgeon. In each instance we used a preliminary hypodermic of morphine, followed by avertin, usually 85 mg. per kilogram of body weight, with 0.5 per cent procaine hydrochloride for local anesthesia. In all but one instance this decompressive operation was completed on both orbits at one stage; on our first patient, two operations were performed.

We expose the frontal bone by a transverse incision from the temporal fossa on one side, across the frontoparietal region immediately behind the hair line, down to the temporal fossa on the opposite side (fig. 2). The scalp is dissected from the pericranium and is reflected forward so that the entire frontal bone on both sides is exposed down to the frontal sinus. Bilateral frontal flaps then are fashioned, the hinge of each being the temporal muscle. A small ridge of bone is left in the midline for the purpose of stabilizing these flaps when replaced. It will be found that such bone flaps retain an adequate vascular supply even though the scalp has been reflected from them. This is shown by the necessity for the use of bone wax, or other agents, to control oozing from the inner surface of the bone.

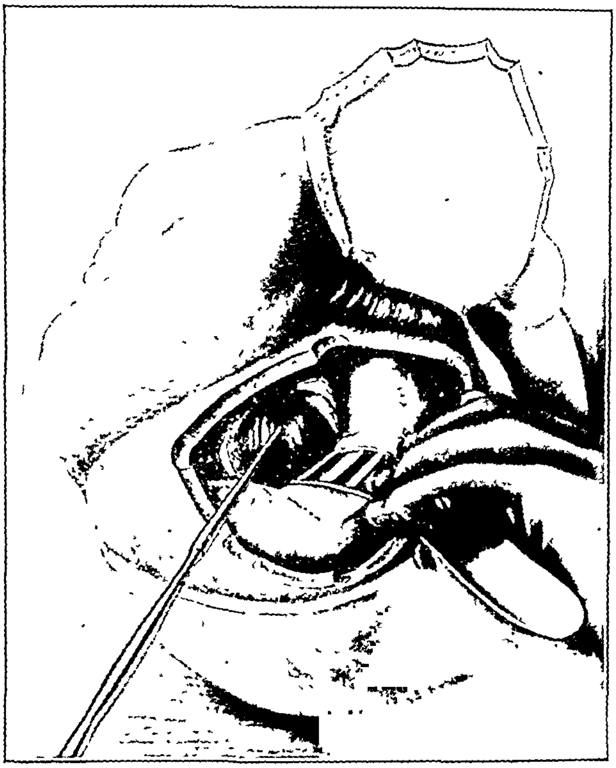

Fig. 5.—Enlarged levator superioris and superior oblique muscles.

Following the reflection of a bone flap, the dura is separated, by means of a broad spatula, from the floor of the anterior fossa in a way familiar to neurologic surgeons as an approach to tumors of the pituitary region. This stripping of the dura from the anterior fossa is carried back to the sphenoidal ridge and the base of the anterior clinoid. Mesially it is continued almost to the cribriform plate. The roof of the orbit then is opened (fig. 3). After carefully separating the orbital fascia so that it will not be opened until the bone removal is complete, we remove the orbital roof by rongeur. The bone opening is carried forward anteriorly to the frontal sinus and laterally to the point where the orbital roof merges into the lateral wall of the skull. Posteriorly, it is continued to the sphenoidal ridge, leaving only a thin line of bone attached to the small sinus, which is harbored in the dural reflection. The roof of the optic foramen and its superolateral margin are removed (fig. 4). Roentgenograms of the foramen, which show its relation to the sphe-

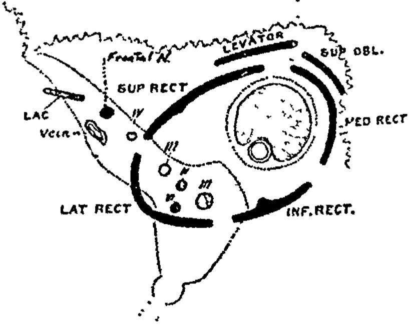

Fig. 6 —Schema to show the position of the annulus of Zinn and its relation to the apex of the orbit. (After S. Whitnall.)

noidal sinus, guide the surgeon as to the extent and direction of bone removal. The orbital contents will bulge through the bone opening as it is enlarged.

When the bone removal is completed, the orbital fascia is opened, care being taken to spare the frontal branches of the fifth nerve. The fat of the orbit varies somewhat in amount, but, in our cases, it has not been increased as stated in the conjectures as to the cause of exophthalmos; nor is it under tension. The orbital content is not particularly vascular.

By blunt dissection the levator superioris and the superior rectus muscles are exposed readily; careful attention should be paid to the fact that their nerve supply comes from below, and the nerve filaments should not be put under undue tension. The internal and external recti likewise may be exposed. The aspect of the muscles varies from a pale, half-cooked appearance to a much deeper color. They are enormously enlarged and thickened, instead of being small ribbons, perhaps 1 mm. or more in thickness and 1 cm. or so in breadth, and have a resistant, rubbery feeling. We estimated that some of the muscles we exposed were from three to eight times larger than normal (fig. 5).

In some patients we carried our dissection downward to expose the capsule of Tenon and the optic nerve as it enters the globe. Ordinarily this is unnecessary. Small fragments of muscle may be taken for pathologic examination; indeed, in the present state of our knowledge of the entire subject, this is advisable. Such specimens should be taken from the margin of the muscle, opposite the entrance of the nerve supply; enough should not be removed to weaken the muscle materially. The orbital fascia having been opened widely in all directions, the ring of Zinn, surrounding the orbital fissure and the optic foramen, may be slit (fig. 6). Usually this is done at the outer margin of the superior rectus muscle.

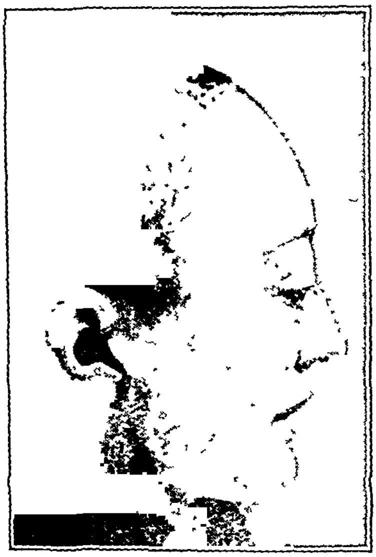

Fig 7.—The scar of operation within the hair line.

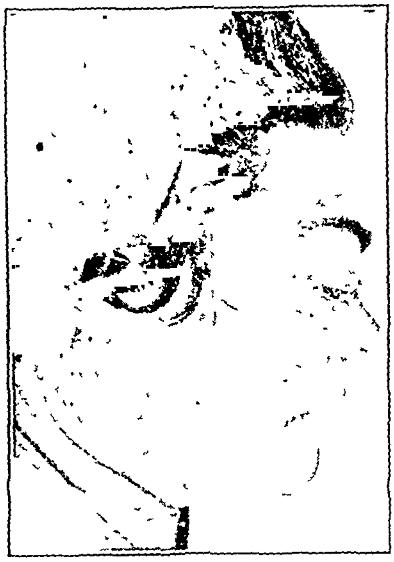

Fig 8.—E H. before operation, showing proptosis and inability to close the lids.

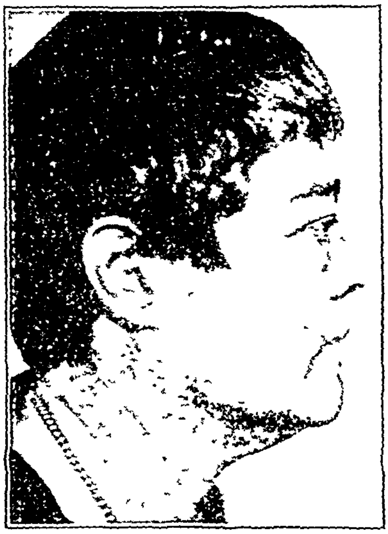

Fig 9.—E H one year after operation. Compare with figure 8.

As a rule hemostasis is not a problem. The orbital content is not vascular and, after oozing from the bone has been controlled carefully, the dura is allowed to come down and rest directly on the orbital content. A similar procedure then is carried out on the opposite side. The bone flaps are replaced and fastened together across the ridge of bone in the midline, the scalp is returned to its former position and is sutured. Separate sutures for the galea and skin are used. The bone openings of the flap, particularly those of the frontal region, are filled in with bone dust or small fragments of bone and the aponeurosis is sutured carefully over them to prevent dimpling of the scalp (fig. 7).

On conclusion of the operation, it will be found that there has been marked recession of the eyes, and that the globes pulsate. Within some hours, edema from handling will occur, and protrusion of the eyes will begin again. This is marked and may be progressive for the first three or four days. During this time the utmost care is needed to protect the cornea. Boric acid ointment for the protruding conjunctiva, careful washing with 2 per cent boric acid solution, and protective goggles are used. After four or five days, there is gradual recession of the edema and, by the end of ten days or two weeks, protrusion of the globes will be found to be less than it was before operation, and the movements of the eye muscles perhaps will be of the same range and degree as before operation. From this time on, there will be steady, slow improvement, both in the range of ocular movements and in the recession of the globes. It has been our experience that this improvement will continue over many months, and, in our most advanced cases, the condition of the eyeballs approached normal only after a lapse of eight months or a year (figs. 8 and 9). In our experience, subjective improvement in vision begins from the fifth to the tenth day and becomes even more striking later. The swelling of the optic disks regresses gradually, and hemorrhages in the retina disappear. Unless a marked state of atrophy has occurred already, satisfactory vision may be expected. Some of those operated on show a faint, persistent pulsation of the globe, not discernible on ordinary inspection, but seen if carefully looked for. Patients ordinarily are unaware of this pulsation and no subjective disturbances of vision result from it.

As to the surgical results obtained, six patients have had bilateral orbital decompressions, that is, twelve orbits have been investigated and treated. Four patients were operated on at the University of California Hospital; one was operated on by Dr. R. E. Semmes of Memphis, and one by Dr. P. C. Bucy of the University of Chicago. From these surgeons communications and reports on their patients and on the pathologic material were received.

There have been no deaths and no postoperative complications other than the temporary edema of the orbital tissues. In all of the patients treated, the results have been gratifying; vision has been restored, optic atrophy has been halted, exophthalmos has decreased and an increased range of ocular movements has followed. Considering the hitherto hopeless outlook for this group of patients, surgical treatment has been singularly gratifying, not only in its results, but in making clear to us the pathologic changes responsible for this type of exophthalmos.

THE END-RESULTS OF SURGERY IN EXOPHTHALMIC GOITER

HOWARD M. CLUTE, M D.
AND
J ROSS VEAL, M D.
BOSTON

The immediate advantages of surgical measures in the treatment of exophthalmic goiter have been convincingly demonstrated. The operation of subtotal thyroidectomy has been made a safe procedure. It is important, however, to learn by careful clinical examination and laboratory confirmation what the ultimate result may be in patients who some years before have had subtotal thyroidectomy for exophthalmic goiter. In a disease that causes such striking effects on various parts of the body, it is valuable to learn whether or not subtotal thyroidectomy produces a permanent improvement, whether the future lives of patients subjected to the procedure are seriously affected by the disease and whether or not the normal course of life is materially altered by the removal of a considerable portion of the thyroid gland.

For the purpose of this study it was determined to ascertain the results of subtotal thyroidectomy for exophthalmic goiter in a series of patients on whom operations had been performed five or more years before the present writing. The use of compound solution of iodine was first adopted in 1924 and 1925; since this made such a definite change in the operability of patients with exophthalmic goiter and in their postoperative recovery, it was felt that a survey of the late results of operation for exophthalmic goiter would best be obtained by starting with patients operated on in 1926, when compound solution of iodine was used as a routine, as it is at present. For the purpose of this study, then, a consecutive series of patients with exophthalmic goiter operated on in 1926 was selected. Since the study was started in the fall of 1931 but was not completed until the spring of 1932, every patient reported on was operated on at least five years before; many of them, over five years before.

Table 1—*Material for Study**

Ninety-seven patients with exophthalmic goiter operated on in 1926	
Consecutive cases	186
Not located	56
Letters only (not used)	26
Examination only (not used)	7
Examination and metabolism used in the study	97

* The cases reported in this paper were, as nearly as possible, consecutive cases in which operation was performed in 1926, followed by metabolic tests and clinical examinations in 1931 and 1932

Letters were sent to 186 consecutive patients with exophthalmic goiter (table 1). Of these we were unable to locate 56, but we succeeded in following 130, or 69 per cent, of these five-year cases. In 26 cases our only information was received by letter. These letters we discarded; we did not use them, because the information was in some measure unreliable. In 7 cases our information came from personal examination of the patient in the clinic, but in these 7 cases we were unable to secure tests for metabolism; these cases, therefore, were also excluded. We have been able to make clinical examinations and metabolism tests of 97 consecutive patients in this follow-up study, which is approximately 50 per cent of all the patients to whom we wrote. In this paper we shall summarize the results of surgical treatment on the 97 patients who have been followed consistently for over five years since operation and have been checked by personal examination and basal metabolic estimations.

It is of interest to note that in 1926, 415 patients were operated on for exophthalmic goiter in the clinic. Five hundred and seventy-four operations were necessary in this group. There were 3 deaths—a mortality rate of 0.72 per cent by patients or of 0.52 per cent by operations. In the clinic these figures still closely represent the yearly mortality average since 1926 in dealing with this type of operation for goiter (table 2).

We have always been impressed with the necessity for careful postoperative examinations of patients with hyperthyroidism, and in dealing with this disease we have insisted, whenever possible, that metabolism tests be taken not only before operation to confirm the diagnosis but also immediately after operation to note the improvement. Furthermore, each patient, after discharge from the hospital, is requested to return every three months during the first postoperative year for clinical examination and metabolism tests. Occasionally patients are unable to return for all 4 tests during the first year after operation, but they usually return for at least 2 tests in the first postoperative year. Of the 97 patients whom we followed in this series, this routine of preoperative metabolism tests and postoperative follow-up metabolism tests for the first year was carried out with relatively few exceptions. We can, therefore, with these repeated examinations, give not only our clinical impression of the severity of the disease and the degree of improvement at varying intervals after the operation but also the metabolic follow-up to check these clinical impressions. This method, we feel, offers a graphic demonstration of the efficacy of surgical measures, something which is available in but few other diseases. Since practically all of the operations on these patients were done either by Dr. Lahey or one of us (Dr. Clute), the end results here cited demonstrate the value of an established treatment that has not changed in any major detail since that time.

In practically every case the basal metabolic rates of these 97 patients were taken the day after admis-

Table 2—*Operative Mortality in Exophthalmic Goiter**

	Cases	Operations	Deaths	Case Mortality, Per Cent	Operative Mortality, Per Cent
1926	415	574	3	0.72	0.52
1927	439	596	4	0.9	0.67
1928	536	676	0	0.0	0.0
1929	448	539	4	0.89	0.74
1930	398	568	5	1.25	0.88
1931	472	648	3	0.63	0.46
Totals	2,708	3,601	19	0.70	0.52

* The figures in the table demonstrate the fact that surgical management of exophthalmic goiter is now a safe procedure.

From the Lahey Clinic

Read before the Section on Surgery, General and Abdominal, at the Eighty-Third Annual Session of the American Medical Association, New Orleans, May 13, 1932 sion to the hospital, following a night of rest. As would be expected, there was a wide range of rates in this group at entrance. Some of those with low rates had been receiving iodine before coming to the hospital, so that their rates were probably not an exact measure of the degree of hyperthyroidism. On the other hand, certain patients in this group undoubtedly had excessively high rates, owing to their nervousness and fear of the test. The average basal metabolic rate for the entire group at entrance was + 54 per cent.

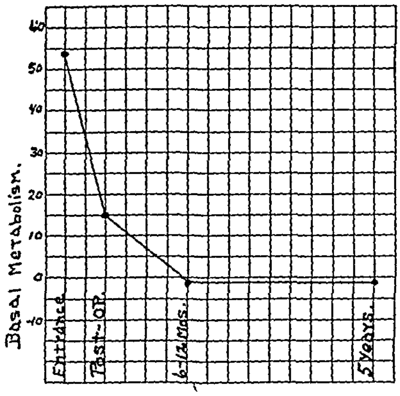

Chart 1.—The average basal metabolic rate of the 97 patients over a period of five years after operation

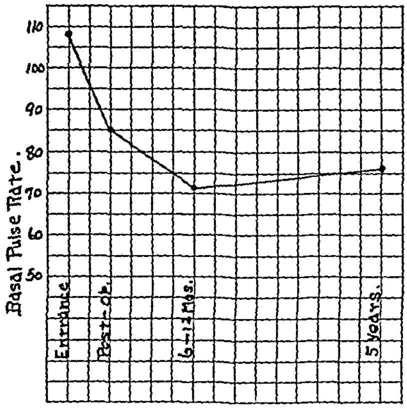

Chart 2.—The basal pulse rate of the 97 patients over a period of five years following operation

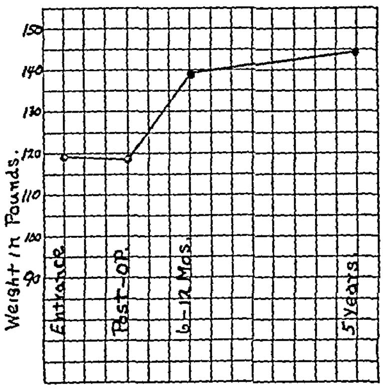

Chart 3.—The average weight of the 97 patients over a period of five years after operation.

After the patients were prepared for operation with compound solution of iodine and rest, a subtotal thyroidectomy was performed. In 35 per cent of cases it was necessary to do this in divided operations. It is generally recognized, and this we have demonstrated to our satisfaction, that subtotal thyroidectomy by divided operations gives the same ultimate improvement in the clinical symptoms and metabolic rates that subtotal thyroidectomy does in a one-stage operation.[1] The average basal metabolic rate of these 97 patients after their final operation on discharge from the hospital was + 15 per cent.

Ninety-three of this group of patients were followed postoperatively with metabolic estimations and clinical examinations at intervals of from six months to a year. The average metabolic rate in these 93 patients at this interval was — 1 per cent.

The final check-up examination that we were able to make on 97 patients from five to six years after operation showed that the average basal metabolic rate for the entire group at this time was — 1 per cent (chart 1).

From this summary of the basal metabolic rates in this group of patients who had had exophthalmic goiter it is apparent that subtotal thyroidectomy produces an immediate return of the basal metabolism to nearly normal, that the metabolic rate reaches normal in from six months to a year after operation in the average patient, and that it is still at a normal level five or more years after the operation has been performed.

It has been definitely shown that the resting pulse rate in exophthalmic goiter roughly parallels the basal metabolic rate. In extremely toxic patients with high basal metabolic rates the pulse rate taken during rest is relatively high, and, correspondingly, in patients with lower metabolic rates the pulse rate is low. In this group of patients we find the basal pulse rate in its course following closely the basal metabolic rate during the period of the disease and in the following years.

In 97 cases the average resting pulse rate at the time of the entrance metabolism test was 108. Following operation the average pulse rate in 97 cases was 85. In the metabolism test made from six months to one year after operation the basal pulse rate in 93 cases was 72. In the final metabolism test, made five years after operation in 96 cases, the average pulse rate was 76 (chart 2).

Marked loss in weight is one of the outstanding symptoms of exophthalmic goiter that permit of analysis and study. In general the more serious the toxicity, the lower the weight; on the other hand, the more complete the return of the patient to normal, the more definite is the gain in weight.

In these 96 cases the average weight on admission was 119 pounds (54 Kg.). Six days postoperatively the average weight for the same group was 118 pounds (53.5 Kg.). This lack of significant variation in body weight during the period of preparation for operation and in the immediate postoperative course demonstrates, we believe, that with the present ideas of treatment of exophthalmic goiter, which include the provision of an adequate intake of food for the increased metabolic requirements, loss of weight at once ceases in the majority of patients when treatment is instituted.

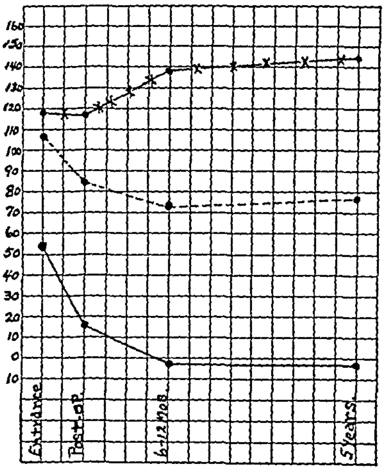

Chart 4.—The effect of subtotal thyroidectomy in exophthalmic goiter. Note the immediate fall of the pulse rate and the basal metabolism in the week following operation and the slight fall in weight at the same time. Following this is seen a definite elevation in weight and a further drop in basal pulse rate and basal metabolic rate in the five year period following operation. The continuous line indicates basal metabolic rate, the broken line, the pulse rate, and the x line, the weight.

The average weight of 92 patients taken from six months to a year after operation had increased to 139 pounds (63 Kg.). In 96 patients in whom the weight was listed from five to six years after operation the average weight was 143 pounds (64.9) Kg.) showing an average gain of 24 pounds (10.9 Kg.) over a period of from five to six years (chart 3).

---

[1] Clute, Howard M.: The Effect of Compound Solution of Iodine and Rest in the Surgery of Exophthalmic Goiter, J. A. M. A. 86: 105 (Jan 9) 1926.

Exophthalmos is one of the prominent effects of exophthalmic goiter, and since it is so disfiguring, it is one of which patients are most anxious to be relieved. In 100 consecutive patients examined in 1926, 62 were noted as having definite and unquestionable exophthalmos preoperatively—an incidence of 62 per cent. Twenty-one of the 100 patients showed exophthalmos five years later.

Table 3.—*Exophthalmos*

100 patients examined in 1926	
Exophthalmos present	62
Exophthalmis absent	38
The same 100 patients examined 5 years later	
Exophthalmos present	21
Exophthalmos absent	79
Of 62 patients having exophthalmos in 1926	
43 showed none five years later	
69.3 per cent of exophthalmos cured	
In 2 patients exophthalmos first appeared after operation	

In 2 of the 21 patients the exophthalmos had appeared postoperatively within a relatively short time before the present writing, and had not been present at the time of the original examination five years previously. Of the 62 patients who had exophthalmos in 1926, in 43, or 69.3 per cent, it disappeared following subtotal thyroidectomy (chart 4). We feel from these figures that we may properly anticipate that 7 of 10 patients having exophthalmos at the time of their first examination will be free of the exophthalmos when surgically relieved of hyperthyroidism. The late occurrence of exophthalmos is explained in one case by a recurrence of slight toxicity. In the other patient there was no obvious explanation for its occurrence (table 3).

Every one dealing with exophthalmic goiter appreciates the fact that myxedema may develop in a certain number of patients following subtotal thyroidectomy. It is because of the possibility of this condition, as well as that of recurrent or persisting toxicity, that follow-up contact with goiter patients who have had hyperthyroidism should be maintained. In this group of 97 patients, myxedema occurred in 3 as a persistent condition; it is still present and requires treatment with thyroid extract. It has been said that myxedema never follows subtotal thyroidectomy for exophthalmic goiter unless marked thyroiditis is present in the gland at the time of operation. One of the 3 patients suffering from myxedema showed thyroiditis, grade II. In neither of the others was thyroiditis reported by the pathologist (table 4).

Table 4.—*Myxedema* *

Patients followed	97
Patients having persistent myxedema	3
Thyroiditis present in patients with myxedema	1
All three patients well under thyroid medication	

* Persistent myxedema occurred 3 times in the 97 patients followed for five years.

All 3 patients with definite myxedema are now well, and it is difficult for us to report their cases with complete fairness in our final analysis of the results of surgical measures in exophthalmic goiter. We believe that they should be considered as patients who are cured of exophthalmic goiter, yet we do not feel that they should be placed in the group with those who are cured and do not require further treatment for myxedema. We are unable to note anything about these patients at the present time that appears abnormal. They feel well, work regularly and enjoy life; nevertheless, they are patients with myxedema following thyroidectomy. They take desiccated thyroid regularly, and therefore cannot be classified as ideally cured.

Four patients in the group had low basal metabolic rates when the metabolism test was made three months after operation. We believe that these patients had transient myxedema. The basal metabolic rates of all have now returned to normal; none of them require thyroid extract; all are apparently well, and we consider them as patients cured of exophthalmic goiter. In the past we frequently felt that if a patient had a metabolic rate of — 16 we should give him desiccated thyroid whether or not he had clinical evidences of myxedema. Recent studies of the blood cholesterol in patients with low basal metabolic rates made in the clinic by Dr. Lewis M. Hurxthal have been most helpful to us in dealing with these patients. In patients having low basal metabolic rates who showed no obvious clinical evidence of myxedema we have found the blood cholesterol normal. If, however, the basal metabolic rate is markedly elevated, it has been established that these patients with slightly low rates must be considered as having myxedema, and that they will show definite improvement on thyroid medication.

Table 5.—*Postoperative Hyperthyroidism in Twelve Patients* *

I. Persisting hyperthyroidism—6 patients
  (a) 4 required reoperation
    (1) 1 was cured
    (2) 1 died (embolus)
    (3) 2 are still toxic but are controlled with compound solution of iodine
  (b) 2 are mildly toxic but are controlled with compound solution of iodine
II. Recurrent hyperthyroidism—6 patients
  (a) 2 required reoperation
    (1) 1 has been cured for three years
    (2) 1 was recently operated on
  (b) 4 are mildly toxic but are controlled with compound solution of iodine

* The incidence of postoperative hyperthyroidism in the 97 patients includes all hyperthyroidism occurring during the five year interval after operation.

From our observation of the patients with myxedema following thyroidectomy and of their ability to work and pursue their regular course of life, we feel that myxedema is not a condition to be feared. While it is undesirable to produce myxedema, it doubtless is preferable to a persistent hyperthyroidism.

The persistence or recurrence of hyperthyroidism after subtotal thyroidectomy for exophthalmic goiter is the most important reason for postoperative estimations of metabolism and postoperative examinations of these patients. We have always known that some degree of postoperative toxicity was present in from 6 to 10 per cent of our patients; at times it was so mild as to be negligible, and at other times so severe as to require reoperation. In our present study, hyperthyroidism was found to have recurred in 12 patients in this group after their first operation had been completed (table 5). We have endeavored to be extremely critical and frank in allocating patients as having persistent hyperthyroidism, and we believe that this figure is, if anything, too high for an average group of postoperative cases. We know that patients with persisting hyperthyroidism are among the first to return in any follow-up study, while patients who are perfectly well are the most difficult to persuade to return.

Hyperthyroidism after thyroidectomy occurs in 2 distinctly different groups of patients having different clinical histories. In one group the hyperthyroidism is clearly *persistent* after thyroidectomy. These patients have a basal metabolic rate which never quite reaches normal after operation, and which in the course of weeks or months persists at this or a higher level. In the other group of patients the hyperthyroidism is definitely and completely cured for an interval of from six months to a year or more after thyroidectomy. This is shown by the complete relief from all clinical evidences of the disease and by a return of the metabolic rate to a normal figure. When hyperthyroidism arises in these patients, we consider it *recurrent* hyperthyroidism.

The patients with persistent hyperthyroidism are those who have been most difficult to cure. In this group of 6, 4 required operations later, and only 1 was cured. Two of these 4 are still toxic, but their symptoms are adequately controlled with compound solution of iodine, and they are able to lead normal lives. One of the 4, a patient with established auricular fibrillation for over five years, died of an embolus eight days following a recent secondary operation on the thyroid gland. The remaining 2 of these 6 patients with persisting hyperthyroidism are still mildly toxic but the condition is being adequately controlled with compound solution of iodine.

In the 6 patients who had a recurrence of hyperthyroidism, 2 required later operations; 1 of the latter has remained well, with a normal metabolic rate, for three years. The other was operaterd on so recently that no report is adequate. The remaining 4 patients with recurrences all had hyperthyroidism of a mild type and their condition is completely and adequately controlled with compound solution of iodine, in daily doses of 10 minims.

Injury to the recurrent laryngeal nerve during the course of operation on the thyroid gland is an accident that may occur and produce most distressing consequences. In any consideration of the results of operation in exophthalmic goiter the occurrence of bilateral paralysis of the recurrent laryngeal nerve should be discussed. This complication did not occur in this series of patients, and has occurred but once in our entire experience with over 10,600 operations for goiter in the clinic. Obviously, then, injury to the recurrent laryngeal nerve in thyroid surgery is not a feature of such danger as to be considered by any one fearful of operating for exophthalmic goiter. Injuries to a single recurrent nerve have occurred, but they have never been sufficiently serious to cause troublesome symptoms.

Injury to parathyroid bodies in the course of thyroidectomy is frequently discussed and is considered as an outstanding danger. In our entire experience with over 10,600 operations for goiter, complete tetany has occurred but 3 times, and transient tetany, 11 times. In the last five years only 4 cases of tetany have been seen, and 3 of these were in secondary operations on the thyroid gland. One case of transient tetany occurred in this group of patients operated on in 1926. This patient was reexamined recently and found to have no evidence of tetany now and to require no treatment for the condition. She has borne a child since the operation on her thyroid gland; following the delivery of the baby she had tetany again for a few days. This was readily controlled with calcium lactate and viosterol administered by mouth, and her blood calcium and a clinical examination now show that she is entirely free from any evidence of the disease. We do not feel that tetany is to be feared as a likely complication of present-day operations on the thyroid.

In the entire group of 134 patients followed by mail and examination it was found that in the five to six year interval since operation 4 had died. It is interesting to note the causes of death in these patients: 2 died of pneumonia at intervals of two and three years after operation; 1 died of cancer of the pancreas some months after operation, and 1 died of nephritis four and one half years after operation.

Table 6.—*Summary of End-Results with Ninety-Seven Cases Five Years After Operation*

Well	82
Well after reoperation or administration of compound solution of iodine	7
Well but requiring thyroid extract	3
Total cases relieved by operation	92 or 94.8%
Toxic but controlled with compound solution of iodine	4
Dead after reoperation	1

In summarizing the results obtained in this group of 97 patients who have been accurately followed, we feel that in 82 patients complete and satisfactory cure was obtained. In 7 other patients slight toxicity is still present, entirely controlled by either secondary operation or compound solution of iodine. In three patients of the group myxedema developed; this was entirely controlled by desiccated thyroid. Four of the patients in the group are still toxic. None of the 4 is in any way incapacitated, and all are working. One of the patients in the group died following a recent secondary operation for recurrent hyperthyroidism and congestive heart failure (table 6). It is, therefore, our belief that 92, or 94.8 per cent, of these 97 patients are cured of their disease by subtotal thyroidectomy, and that this figure may be assumed to be a fair estimate of the probability of cure of exophthalmic goiter by adequate surgical measures.

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. DINSMORE, DRS. NAFFZIGER AND JONES, AND DRS. CLUTE AND VEAL

Dr. R. E. Semmes, Memphis, Tenn.: A patient on whom I operated for progressive exophthalmos had had a subtotal thyroidectomy a year before, with relief of all his symptoms except the exophthalmos. I first saw him with his eyes protruding so that the lids would not cover the cornea, and there was already some desquamation from exposure. His vision had been reduced to 10/200 in the left eye and 15/200 in the right eye, and it was necessary for him to be led. The exophthalmos was greater in the left eye. With the experience of Drs. Naffziger and Jones in mind, I turned down the usual transfrontal flap on the left side, and when the orbital roof was opened the capsule of the eye bulged markedly. On opening the capsule I found that there was not only no increase in the orbital fat but almost no orbital fat present. The muscles were pale and edematous in appearance, as in the case of Drs Naffziger and Jones, and they were estimated to be approximately ten times the size of the normal. After I removed the roof of the orbit and the top of the optic foramen and closed the flap, the patient's eye had gone back to the normal position on that side. There was a good deal of swelling for a few days after the operation, but this subsided rather rapidly. At present, with the recession of the left eye, the vision has returned to normal on that side. In the right eye the vision is now reduced to 10/200. The basal metabolic rate is subnormal (—15). The blood cholesterol is up to about 390 and there are other evidences of myxedema. Therefore with the idea that this condition might be associated with myxedema, I have administered thyroid extract, without any benefit. I have also continued the dehydration without much benefit and am therefore going to resort to operative procedure again.

Dr. E. R. Arn, Dayton, Ohio: I shall limit my discussion to that portion of the paper of Drs. Clute and Veal which refers to persistent hyperthyroidism. Those who have had a wide experience in the field of goiter surgery have encountered from time to time cases of toxic diffuse goiter in which the symptoms of hyperthyroidism have either persisted or recurred following adequate subtotal thyroidectomy. In such cases it has been common practice to do a second exploration of the thyroid area. In some instances a considerable amount of thyroid tissue, in excess of that which was left at the time of the first operation, will be found. Radical removal of the remaining thyroid tissue will result in a disappearance of the symptoms of hyperthyroidism in a majority of such cases. On the other hand, the secondary operation will occasionally reveal only a few islands of thyroid tissue remaining after the first operation, and the surgeon feels reluctant to remove any of this tissue. The surgeon may satisfy himself by examination of the thyroid area that further operation on the thyroid will be useless. Common experience has revealed that the continuous administration of compound solution of iodine is of little or no avail in such cases. For this type of case it has become apparent that some new approach to the problem is indicated. Stimulated by the results obtained by Crile, following suprarenal denervation in such cases, I have subjected a small group of patients of this type to this operation, with uniformly favorable results. A complete report of my experiences with the Crile operation will be published in the near future. Three of the patients on whom bilateral suprarenal denervation was done were relieved of persistent exophthalmos in addition to the general improvement as related to their hyperthyroid symptoms. It has long been recognized that the suprarenals and the sympathetic nervous system are involved in the Graves syndrome. Suprarenal denervation appears to provide a new and effectual method for further controlling the sympathetic nervous system imbalance and the concomitant endocrinal dysfunction.

Dr. Donald Guthrie, Sayre, Pa.: I am fully in accord with what Dr. Dinsmore says as to the familial tendency in goiters seen in young children. I also believe that infection plays an important part. One sometimes becomes almost weary in examining case after case brought by frightened parents who have been told by a school examining physician that their child has a goiter and needs operation. It is well known that these are largely the harmless adolescent goiters, but it must be remembered that every once in a while as a result of school examination one of these children is picked up and referred early. I should like to ask Dr. Dinsmore just how much gland he leaves behind in these cases. It has always been my fear of throwing some of these children into myxedema. I would far rather get along with a persistent mild case of hyperthyroidism following operation than to have myxedema as a complication. It has been my practice for a long time to leave behind nearly two times as much gland as I would in an adult showing the same amount of symptoms, for one never knows just exactly the demands that may be made on the thyroid in the future. I should like to ask Drs. Clute and Veal what their plan, if any, is about the eradication of foci of infection following operation, and also just how much the normal activities of their patients are limited, and further if they can report the average basal metabolic readings just before operation; in other words, what they believe is the time to operate on these patients after a period of preparation.

Dr. R. M. Howard, Oklahoma City: Exophthalmic goiter in children does not occur frequently but is occasionally seen. In 300 recent cases of exophthalmic goiter reviewed I have had to deal with but four cases. One was a white child aged 6 years, another was 11 years of age, another 16, and a Negro girl was 14. All had the typical symptoms of the disease of a rather severe degree. The percentage of cases seems small. Oklahoma City is rather out of the endemic goiter belt. In the presence of persistent or progressive exophthalmos following operation I have been almost helpless, not only in my efforts to offer relief but in being able to offer myself or my patients a satisfactory explanation for its occurrence. The work of Drs. Naffziger and Jones is interesting and if the cause of the condition, as brought out by them, proves to be the rule, a remedy for the more severe cases is available. Perhaps preserving the venous circulation in the neck may be of prophylactic value. The results of surgical treatment in exophthalmic goiter, while not entirely satisfactory, when compared with the results of other forms of treatment are so much better that little room for argument is left. Statistics such as those presented by Drs. Clute and Veal go far in confirming this view. However, all men doing goiter work have their cases with persistent symptoms, their recurrences, and their cases of hypothyroidism; the first two conditions require further operation and the last often requires continued administration of thyroid extract. The state of the patient in any of these conditions is not very satisfactory. Nor is the explanation of the occurrence of these unsatisfactory states always clear. The amount of gland left following operation is important. Complications existing in the gland itself, as well as the likely future demands to be made on the gland, must be carefully considered. The results of surgical treatment in exophthalmic goiter are not dependent alone on technical skill. Careful judgment acquired by experience is necessary in the care of these patients, not only in their preoperative preparation and during the operative procedure, but in their supervision for many months postoperatively.

Dr. Willard Bartlett, Jr., St. Louis: The results reported by Dr. Dinsmore and Drs. Clute and Veal constitute a mark to shoot at. In my opinion, the end-results of Drs. Clute and Veal are largely a reflection of the continued supervision of their patients, for recurrences are primarily the consequence of the patient's habits of life; these depend to a large extent on the group of persons with whom he lives. I am interested more in the ratio between preoperative and postoperative deaths in any given goiter service, as an index of the problem confronting the surgeon, than on operative mortality alone. From 1926 to 1930, 38 per cent of my goiter deaths occurred before operation and 62 per cent afterward. But during the past twelve months 84 per cent were preoperative and 16 per cent postoperative. This marked improvement following the previous study is due to one thing, better estimation of the patient's ability to withstand operation. The most valuable agent in bringing about this change has been development of the test of ability to hold the breath as a criterion of operability. A word on the paper of Drs. Naffziger and Jones: I have had four cases of recurring exophthalmos in the past five years. Two outstanding features in each of them were hypothyroidism and psychic shock. Early cases should be studied comprehensively, especially from a physic and metabolic standpoint, and treated accordingly. One man who had almost complete loss of vision in his right eye for one year improved slowly on thyroid feeding and now, after five years, has almost perfect vision and no exophthalmos. This was before a resource was available in the operation that Dr. Naffziger has devised. On the basis of that and a similar result obtained recently in which the intense edema around the orbit was apparently a part of the general edema of a marked myxedema, which responded promptly to thyroid, it is worth bearing in mind that if these patients can be got early and their exact status determined when exophthalmos appears, a certain group of them is going to be prevented from going over into the later stages with the persistent and unchangeable results in the orbit due to chronic lymphedema and fibrosis.

Dr. Frank H. Lahey, Boston: There are one or two points which I might make to stress what I have always said, and that is the need of leaving a considerable amount of thyroid tissue in children. All of these men who have spoken about thyroidectomy in children realize but have not stated the reason; namely, that the thyroid is so necessary for development that the penalty of myxedema in a child is much higher than in an adult. One should take myxedema very seriously even in adults. The complacency with which many men who are doing thyroid surgery face myxedema, I believe, is wrong. I feel strongly that the patients who have myxedema postoperatively are never quite the same psychically as those who have sufficient thyroid to meet the variable needs of thyroid secretion. As to the question of recurrent hyperthyroidism, I should like to present another practical point based on my experience of not infrequently leaving too much thyroid tissue. One cannot depend on palpation of thyroid remnants to demonstrate whether or not too much thyroid has been left. The thyroid remnants following subtotal thyroidectomy have a way of sinking into the groove between the esophagus and the trachea deep in the neck so that they are not readily palpable. Therefore, when one has clinical plus metabolic evidence of persistent hyperthyroidism, one does not need to be deterred from exploring the neck because one cannot find remnants, because in a great majority of instances when the neck is exposed one will find remnants of considerable size, the removal of which in the majority of cases will produce relief or cure. There is one warning further, and that is that a higher percentage of tetany must be anticipated, and a higher percentage of recurrent laryngeal paralysis in operations in persistent and recurrent hyperthyroidism. I should like to call attention to one other point. Since Catell and Mason in our clinic have proved that one can successfully transplant parathyroids, it becomes the obligation of every surgeon who is removing thyroids to search carefully for the parathyroids, and when they are found not to send them to the laboratory and be interested in examining them under the microscope, but to transplant them into the sternocleidomastoid muscle, where I feel certain they will take and often prevent postoperative tetany.

DR. HOWARD C. NAFFZIGER, San Francisco: Two have mentioned the fact that these patients have shown a normal or low basal metabolic rate. In all the cases reported in the literature, one finds that this is true. Most of them have received thyroid, but the exophthalmos has not been checked. It is possible, however, that in milder cases of progressive exophthalmos it might be helpful. I should like to impress on those who are doing thyroid surgery that it is desirable to secure extrinsic eye muscles from patients who die with exophthalmos from exophthalmic goiter. It is evident why there is so little opportunity to secure these after hearing the paper of Drs. Clute and Veal, the mortality is so low. It is desirable to determine whether these muscles are normal or large, whether they have edema, or whether they show any inflammatory change whatever. It is interesting to speculate on the cause of this inflammatory change in the muscles. In myasthenia gravis, similar changes have been reported in the extrinsic eye muscles. It might be recalled that enlargement of the thymus has been found in that disease. Enlargement of this gland has not been present in the cases of progressive exophthalmos that we have studied. The changes in the eye muscles are also similar to those in the heart muscle in thyroid disease; they are like the changes seen in the heart muscle in rheumatic fever, and they have points of similarity to the changes that are seen in the muscles in Volkmann's palsy and in the experimental instances of chronic venous obstruction. We are carrying on some experimental work in that connection. There have been instances of exophthalmos reported in rabbits, produced by performing a thyroidectomy and following it with thyroid feeding. This has not been confirmed as yet.

DR. R. S. DINSMORE, Cleveland: I am sorry that I did not mention anything about technic in the discussion. It is quite true, as Drs. Lahey and Guthrie have pointed out, that one must leave more thyroid tissue in these children. They are more prone to develop hypothyroidism after the operation, and I have made it a routine practice to leave, as Dr. Guthrie has stated, approximately twice the amount that I would leave in a similar case in an adult.

DR. HOWARD M. CLUTE, Boston: Dr. Guthrie inquired as to our plan of removal of foci of infection in exophthalmic goiter patients. It has been our feeling and our practice that the prime lesion which was upsetting these patients was their hyperplastic thyroid, and we have never had sufficient proof that the fundamental cause of hyperthyroidism was infection. We therefore undertake first the cure, as rapidly as possible, of their hyperthyroidism. Occasionally operations must be delayed because of some acute infection, which we feel is a serious contraindication to operation; but in nonacute infections we wait until the hyperthyroidism is controlled before we attack the infection. In past years we have been insistent that during the first year after operation the patient's activities should be distinctly limited. We have forbidden pregnancy, we have insisted that patients go to bed early at night and that they do not undertake any strenuous business or social efforts. In recent years we have become more lenient and we are coming to think that when we remove an adequate amount of hyperplastic tissue we cure the disease and that the patients are normal relatively soon after the procedure is over. It is not at all uncommon now for these patients to return to their full duty within certainly three months of the time of operation. The average drop in basal metabolic rate in our experience in the preoperative period of preparation is from 30 to 40 per cent, or even more. We do not depend on the drop in metabolism in deciding as to the time for subtotal thyroidectomy. Many patients who are mildly toxic, who are not severely ill, we operate on about the eighth or ninth day. In patients who are severely ill, regardless of their metabolism (and many of the sickest patients with the apathetic type of hyperthyroidism which Dr. Lahey has discussed will not have high basal metabolic rates), operative procedure must be delayed until we are clinically impressed with the fact that they are well able to stand operation. I think that the preoperative metabolism that is particularly significant is the one which does not come down but which goes up. The patient who after hospitalization and treatment with iodine and rest has an increasing metabolism and pulse rate and a falling body weight is a most serious risk. In these cases surgery must be delayed until improvement is evident or must be adopted as a last resort and with full recognition of its seriousness.

MILK IRRADIATED BY THE CARBON ARC LAMP

A CLINICAL AND LABORATORY STUDY OF RICKETS

A. F. HESS, M.D.
AND
J. M. LEWIS, M.D.
NEW YORK

In the course of the past five years we have reported our experiences, clinical as well as experimental, with various activated substances.[1] The first of these communications dealt with irradiated cholesterol, ergosterol, yeast and dried milk. Those which followed were concerned more particularly with the therapeutics of irradiated ergosterol (viosterol), with its dosage and standardization. Last year a somewhat different aspect was considered,[2] and a clinical test was reported of the milk of cows which had been fed irradiated yeast. Concurrently with these various clinical papers, communications have been made, in some instances in cooperation with other laboratories, dealing more particularly with laboratory or technical features. The most recent one, published in conjunction with Supplee and Dorcas, gave in detail the energy requirements for the antirachitic activation of irradiated milk[3] and showed the high degree of potency of activated dry milk. The present paper concerns itself more especially with clinical experiences with an irradiated fluid milk which has been activated under the most carefully controlled physical conditions.

3. Supplee, G. C.; Dorcas, M. J., and Hess, A. F.: Irradiated Milk: The Energy Requirements for Antirachitic Activation, J. Biol. Chem **94:** 745 (Jan.) 1932.

The subject of the antirachitic activation of milk by means of ultraviolet rays is no longer new. In March, 1925, it was reported: "Experiments which we have recently carried out would lead us to believe that milk can be activated, and that this property may be evident in infants, who, unlike rats, are not protected by a mere increase in the phosphorus in the dietary." [4] The year preceding, we had stated that small amounts of irradiated milk gave uncertain results in protecting rats from rickets. Since this time, clinical reports on milk treated in this manner have been numerous and ever increasing. The first, to our knowledge, was that of Cowell [5] in England; in this country, Kramer [6] published an early paper which recorded favorable results with this new therapeutic agent; in Germany, Scheer [7] has repeatedly drawn attention to the value of milk that has been irradiated by an apparatus that makes use of a special mercury vapor lamp; in fact, he introduced milk of this kind on a large scale in the city of Frankfurt. In Switzerland, Wieland [8] has urged the adoption of irradiated milk as a food for infants. It may be added that Daniels and her collaborators [9] have extended these clinical observations by demonstrating that an intake of irradiated milk is associated in infants, with exceptional retention of calcium and phosphorus.

From a technical point of view the irradiated milk that we fed, both fluid and dry, differed markedly from that which has been employed by others. In the first place, a carbon lamp of the flaming arc type was used for activation instead of a mercury vapor lamp, and furthermore the character and the amount of radiant energy were carefully controlled and measured. During a preliminary test of two years, milk had been subjected to a series of mercury vapor lamps, but this method was found to be undependable, owing largely to irregularities in the energy output of the lamps. The details in regard to the carbon arc lamps used for activating the milk that we tested this year will be found in the paper to which reference has been made.[3] These data may be summarized by the statement that a C carbon was employed and that a total of about three and a half million ergs, between 2,000 and 3,000 angstrom units, were applied per cubic centimeter of milk for a period of sixteen seconds. With a suitable quality and quantity of radiant energy, the antirachitic properties of milk can regularly be increased within a few seconds. The rate of vitamin D formation in milk and the quantum efficiency of the reaction are greatest during the very early stages of the process, and although up to certain limits the degree of antirachitic potency that can be imparted to milk bears a direct relationship to the amount of energy applied, beyond these limits additional energy does not increase the vitamin D content proportionately. The dried as well as the fluid milk contains approximately 50 rat units per liter. There is no possibility of elaborating a product of excessive potency by means of irradiation. According to Supplee and his collaborators,[10] the concentration of vitamin D in milk irradiated in this way is equivalent to about 0.0025 mg. per liter. Without going into the details of these calculations, it is clear that only by subjecting the milk to well controlled and definite amounts of radiant energy can one hope to elaborate a product of fairly constant antirachitic potency. It should be added that this milk suffered only an insignificant loss of vitamin A in the course of irradiation.

Our investigation was conducted under conditions very similar to those of last year when the so-called irradiated yeast milk was fed. In other words, the infants were about 1½ to 6 months of age, somewhat over 100 being selected from two baby health clinics of the department of health in New York. Thorough clinical examinations were carried out from time to time, the infants were weighed regularly thereafter, and frequent roentgenograms of the wrists were taken, for which we are indebted to Mr. Siegel of the Meinhard Memorial Health Center. Throughout the entire period, which extended from the beginning of January to the end of March, careful follow-up work was carried out by a full time nurse whom the commissioner of health assigned to assist in this study. The babies took about 24 to 32 ounces (750 to 1,000 cc.) of milk a day, which was supplemented by cereal and vegetables for the older group. A large number of the infants were Negroes, mostly Porto Ricans, a circumstance that rendered the test especially severe. In addition to these infants in the clinic, a smaller number were observed in the Home for Hebrew Infants, where they could be studied continuously under conditions that were susceptible of control and where observations could be checked by chemical analyses of the blood.

* "Angular beading," not "rounded beading."
† Almost + beading.

The results were clear cut, as was the case last year, and may be summarized in a few words. Of the thirty-six babies that presented no evidences of rickets in January, all but one remained free from roentgenologic signs of rickets. The essential data of these infants are presented in table 1. The sole exception was, as might be supposed, a premature baby. This infant was cared for in the Home and weighed but 4½ pounds (2 Kg.) at birth and 6 pounds 5 ounces (2.8 Kg.) when it was 2 months old and first given irradiated milk. It grew with remarkable rapidity, especially in length, measuring 19⁹⁄₁₀ inches (50 cm.) at 2 months of age, 22 inches (55 cm.) at 3 months, 23⁹⁄₁₀ inches (60 cm.) at 4 months and 25³⁄₁₀ inches (63 cm.) at 6 months. As has been repeatedly emphasized, premature babies must be regarded as a distinct group that cannot be prevented from developing rickets by any antirachitic therapy, except perhaps by the use of exceedingly large amounts of viosterol. In connection with this study, it should be added that, although rickets was regularly warded off from a roentgenologic point of view, the development of craniotabes could not always be prevented nor the formation of a "rosary" (beading of the ribs). It is our experience, however, that these two lesions come about in spite of all antirachitic therapy—breast feeding and liberal doses of cod liver oil or of viosterol. The beading that develops is, however, not of high degree and is often "angular" rather than "rounded" in character.

The other and larger series consisted of infants in whom evidences of rickets were found at the outset. We had not intended to carry out an extensive curative experiment, but on examining the entire group in January it developed that fourteen showed definite signs of rickets by the roentgen rays and that forty-eight others presented clinical evidences of rickets, although characteristic signs at the epiphyses were lacking. Our therapeutic results, reproduced in table 2, with the treatment of "roentgenographic rickets" will be observed to have been highly satisfactory. Definite signs of healing were brought about within a month or six weeks even in Negro babies. This is well demonstrated in the accompanying illustrations.

The results in the larger group, which had merely "clinical rickets," in contradistinction to "roentgenologic rickets," were equally gratifying. The data of these cases are not presented in tabular form for lack of space and because curative effects cannot be satisfactorily demonstrated except in relation to objective evidence such as the roentgenogram. The criteria of healing were recession or angulation of the beading of the ribs, diminution of craniotabes, or intensification of calcification of the epiphyses. Once more it should be stated that the advance of craniotabes often could not be stayed, which was found to hold true even when a fortified cod liver oil was given. It should be emphasized that we have reference to the eradication of roentgenologic rickets, of rickets of moderate and severe degree, and that there is a very mild form characterized by definite but minor clinical manifestations which cannot be prevented by any of these antirachitic measures. As has been pointed out from time to time,[11] it is the realization of this fact, which must be evident to all who have closely followed the incidence of rickets in the clinic, that leads us to believe that in the etiology of this disorder there is a factor quite apart from a lack of vitamin D, a factor which has not yet been fathomed. Pfaundler[12] has expressed a similar view.

---

[11] Hess, A. F., and Weinstock, Mildred: A Study of the Antirachitic Factor in Human and in Cow's Milk, Am. J. Dis. Child. **34**: 845 (Nov.) 1927.

[12] von Pfaundler, M.: Neueres über Rachitis, München. med. Wchnschr. **74**: 659 (April 22); 721 (April 29) 1927.

Our observations may be summarized by the simple statement that milk irradiated in this way proved to be highly satisfactory in the treatment of rickets both from a prophylactic and from a curative point of view. As will be understood, it is not possible to draw a reliable comparison between the efficacy of activated milk and that of the "yeast milk" which was used in a similar study a year ago. It is certain, however, that the activated product was at least as efficacious. A more extensive experience, particularly one in which the two types of therapy are carried out at the same time and under similar clinical conditions, will be necessary in order to enable a more exact comparison.

* "Angular beading," not "rounded beading."

From the very introduction of irradiated ergosterol (viosterol) great confusion has been caused by uncertainties and difficulties in regard to the standardization of the product. In 1929 we expressed ourselves strongly against a standardization based on milligrams, in other words a gravimetric unit, and showed that a milligram of several preparations differed widely in strength. It was suggested that "the only way to make progress in the field so that irradiated ergosterol is rendered suitable for therapeutic use is to standardize preparations on the basis of animal tests."[1] Exception also has been taken to the method of expressing the potency of viosterol in terms of cod liver oil, because a method of this kind postulates that the activity of cod liver oil and viosterol is the same for infants as for rats. In 1930 we reported clinical observations which showed that an assumption of this kind did not accord with the facts and that much more viosterol was needed to protect infants than would be expected, judging by bioassays of the two antirachitic agents.[1] It was suggested, therefore, that instead of making use of cod liver oil as the basis of unitage it would be preferable to express the potency of viosterol directly in terms of rat units. The investigation carried out in the clinic last year[2] clearly showed that this method, although useful for standardizing various preparations of viosterol, led to erroneous results when applied to a comparison of viosterol with "yeast milk" or with irradiated milk. For example, the relative potencies, as expressed in rat units, of "yeast milk," of cod liver oil and of viosterol which were found to afford protection to infants was in the proportion of 1 : 1.25 : 5.2. These figures were based on giving a quart of "yeast milk," 3 teaspoonfuls of cod liver oil or 10 drops daily of viosterol, which, as far as can be judged, is preventive dosage of these three antirachitic agents; they represent approximately 160, 200 and 800 rat units. In other words, a smaller number of rat units of "yeast milk"—milk from cows that had been fed irradiated yeast—was required than of cod liver oil or of viosterol. At that time we did not wish to complicate the subject still further by raising the question of the position of irradiated milk in relation to unitage, contenting ourselves with a pre-

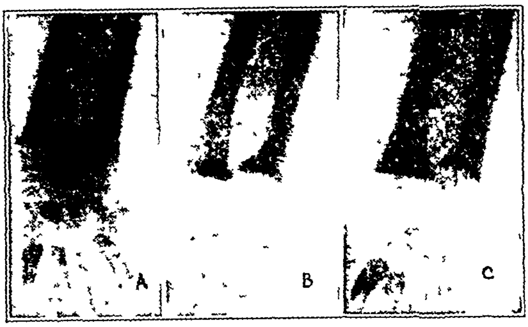

Fig 1.—Therapeutic results with irradiated dry milk *A*, Feb 9 (begun), *B*, March 3 (three weeks later), *C*, March 24 (three weeks later).

liminary statement to the effect that "irradiated milk is also exceptionally potent in regard to the number of rat units which it contains per liter." Our recent clinical and laboratory tests of milk activated by means of the carbon arc lamp, under controlled conditions, have strengthened the conviction that this product belongs in the category of yeast milk and cod liver oil rather than in that of viosterol. A quart, or even less, of this milk suffices to protect infants from rickets, notwithstanding the fact that this quantity contains only 50 units of vitamin D as assayed by the standard rat technic. Others have felt this discrepancy between laboratory standardization and the clinical results obtained with irradiated milk. Watson[13] attributes its effectiveness to the "vital" factor in activated milk, a certain something which is not measurable by the established laboratory tests. It is not possible, at the present time, to state in definite terms the nature of this distinction between various antirachitic agents. For the time being we must be satisfied with a realization of the existence of this peculiar biologic phenomenon, which is implicit with the inevitable conclusion that biologic assays, however valuable for a comparison of the potencies of antirachitic agents of the same kind, cannot be relied on in estimating the clinical value of antirachitic preparations as different as viosterol and irradiated milk.

Recently, Shelling and Asher[14] have expressed the opinion that it is "not reasonable" to assume that cod liver oil is more efficacious than viosterol in preventing infantile rickets. They base their conclusion on the fact that the antirachitic potency of these two therapeutic agents is comparable when tested on the rat. However, in view of the fact that the standard for viosterol is computed in terms of cod liver oil in one and the same animal, it is evident that this method of assay cannot be resorted to in determining whether these two agents vary in activity for infants. It is universally admitted that cod liver oil is definitely and notably more potent than viosterol in preventing leg-weakness in chickens. What we are interested in primarily is, of course, the action of these two substances in relation to the rickets of infants. In a report published about two years ago,[15] it was stated that to protect against or to cure infantile rickets about six times as much viosterol was required as cod liver oil. It may be added that subsequent experience has served only to fortify us in this conclusion. Such marked differences cannot be attributed to "different conditions of diet or environment." In the first place the environment of the infants in question was that of an institution and therefore eminently uniform. Secondly, the diet necessarily consisted either entirely or almost entirely of milk, which implies that, irrespective of dilution or formula, the Ca: P ratio was in all cases the same or almost the same. This holds true of the dietary of all infants about 3 or 6 months of age and is not disturbed significantly by the addition of the usual amounts of cereal or of vegetable. Moreover, the striking instance which we have cited of an infant which developed rickets, in spite of receiving twenty drops of viosterol daily, which is supposed to be *the equivalent of ten teaspoonfuls* of cod liver oil, but showed signs of healing after being given six teaspoonfuls of cod liver oil for a period of three weeks, is highly significant. Others have come to a similar conclusion in regard to the relative merits of these two valuable antirachitic agents. Shelling and Asher have demonstrated, however, that there is no distinction in antirachitic effect between cod liver oil and viosterol in the rickets induced in rats by means of a low phosphorus or a low calcium ration.

The number of antirachitic agents has grown so large that it would seem worth while to stop and pass them in review in an attempt to appraise their value in the prevention and cure of rickets throughout the community. The most outstanding are (1) irradiated milk, fluid and dry, (2) "yeast milk," (3) cod liver oil, (4) viosterol, (5) irradiated yeast, (6) direct ultraviolet irradiation, and concentrates and combinations of these products. It is evident that these various measures must differ not only in their specific virtue but also in their applicability according to whether one is considering individuals or a community, whether the community is rural or urban, and at all events according to the cost of the preparation.

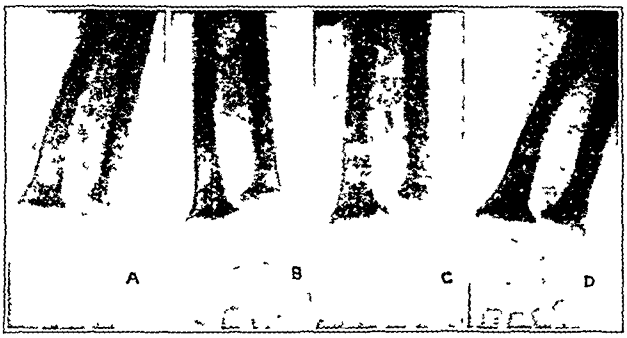

Fig. 2.—Therapeutic results with pasteurized irradiated fluid milk *A*, Jan 25 (begun), *B*, March 2 (five weeks later), *C*, March 15 (two weeks later), *D*, March 29 (two weeks later)

Beginning with a consideration of irradiated milk, it should be emphasized that this therapeutic agent has two inherent advantages. First, in that milk is the essential food for all infants, the indispensable and basal article of diet throughout the rachitic age, and furthermore in that, owing to its unequaled content of calcium and phosphorus, it is outstanding in connection with calcification. At the outset it should be mentioned that there does not seem to be any danger of giving excessive doses of any of these antirachitic preparations to the growing child. A series of recent biologic tests showed that 10,000 or 15,000 times the therapeutic dose of any of these five preparations could be fed to young rats without bringing about hypercalcemia; for this purpose, of course, concentrates had to be prepared. Irradiated milk also has the advantage of being inexpensive. It is estimated that the additional cost of the activated milk which we fed this year was but one twenty-fifth of a cent per quart.

[13] Watson, Chalmers: The "Vital" Factor in Diet A Theory of the Nature of Vitamins, Edinburgh M. J **38:** 91 (June) 1931

[14] Shelling, D H, and Asher, D E Bull Johns Hopkins Hosp. **50:** 344, 1932.

[15] Hess, A F.; Lewis, J M, and Rivkin, Helen Newer Aspects of the Therapeutics of Viosterol (Irradiated Ergosterol), J. A. M. A. **94:** 1885 (June 14) 1930.

It is probably true that the use of this therapeutic method does not provide a constant intake of vitamin D. It should be added, however, that assays of irradiated milk, carried out in the course of the winter, have not shown significant variations in potency. Inconstancy of supply is an outstanding characteristic of the vitamins, for example of the antiscorbutic factor, which varies largely according to individual caprice, according to the consumption of fruits and vegetables. In respect to the antirachitic factor, which is furnished in largest measure by the rays of the sun and varies greatly from hour to hour, season to season and locality to locality, our daily quota is eminently capricious. This criticism of the product is, therefore, quite irrelevant. Nor is there the slightest basis for believing that, in the course of "flash irradiation" by a carbon arc, any harmful products are elaborated. As a substitute measure, the addition of irradiated ergosterol to milk has been suggested. This method would involve the danger of error at the dairies in the course of adding the supplement, and, furthermore, presupposes that irradiated ergosterol is maintained in uniform solution throughout the milk. Moreover, as stated, it necessitates, on account of the comparatively low "efficacy factor" of irradiated ergosterol, giving several times the number of vitamin units required when irradiated milk is given. It should be borne in mind that the addition to a food of crystalline vitamin D, however pure, has yet to be shown to possess any advantage over a similar food which has been activated by short exposure to ultraviolet radiations.

On the other hand, there are definite limitations to the adoption of irradiated fluid milk. It is clear that it is adapted for use in cities and cannot be prepared for rural communities. According to the latest census, almost one fourth of the population of the United States, in other words, 36 millions, live in cities of over 100,000 population. It is to communities such as these that a product of this kind would seem to be limited. In a city such as New York, where approximately 500,000 quarts of grade A milk is used daily and where four fifths of the milk of this grade is pasteurized in the city, there is an especially favorable opportunity to combine pasteurization and irradiation of milk for babies and children. It may be added that dry milk, milk dried by the roller process, was found last year to be very effective in protecting against or curing rickets and that this product maintains its potency for a period of many months. Irradiation could well be extended to evaporated milk which is given to babies on a large scale in small and distant communities where the need of antirachitic therapy is not realized and its application would be difficult.

Milk obtained from cows that are receiving large quantities of irradiated yeast ("yeast milk") is likewise of value in the prevention of rickets. During the past year this measure has been used at certified farms in New York, Boston and Philadelphia and is about to be adopted elsewhere. It is a measure that is especially applicable to the certified farm where the ration of the cows is thoroughly controlled and one can be certain that a potent yeast is fed in proper amount and, more particularly, where frequent biologic assays of the milk can be carried out. Perhaps its application can be somewhat extended to grade A farms which provide a milk that is not certified and is much less expensive. It should be added that during the past winter we continued a certain number of infants in the baby health station on "yeast milk" for the second year and found that they thrived excellently, that none of them developed rickets in the course of the winter, and that the bones showed excellent calcification on roentgenologic examination.

Cod liver oil, like the antirachitic milk preparations, is reliable in preventing rickets excepting in its mildest form. It has been especially recommended on account of its high content of vitamin A, which by some has been termed and regarded as the "antiinfective vitamin." Without entering into a discussion of this subject, which has been considered elsewhere, it should be stated that this term is a misnomer, as neither vitamin A nor cod liver oil is able to prevent respiratory infections. Moreover, grade A and the better grades of milk contain from 1,000 to 2,000 vitamin A units per quart, which should be a sufficiency of this nutritional factor. Possibly cod liver oil contains some factor of which we are not yet cognizant—a possibility which has been referred to elsewhere but which cannot be stated more definitely as the result either of clinical observation or of laboratory test. The main disadvantage of cod liver oil, which has stood in the way of its general acceptance by mothers and children, is its disagreeable taste and odor.

The most potent of all antirachitics is viosterol. It should therefore be singled out for the cure of rickets and for its prevention in the premature infant, which often resists all other measures and is a disorder quite outside the ordinary category. Like cod liver oil, irradiated dry milk and viosterol are suited especially for the rural community in which irradiated milk or "yeast milk" is not applicable. Communities of this kind, containing less than 2,500 inhabitants, harbor 53 of the 122 million total population of the United States.

Irradiated yeast, which one of us recommended some five years ago,[16] has been used to only a small extent. Its disagreeable taste is most difficult to disguise. It is possible that this antirachitic agent or viosterol will be found suitable for nursing mothers in order to protect their infants from rickets and to prevent the withdrawal of lime from the bones, a reaction so commonly associated with lactation. However, if available, irradiated milk would be preferable for this purpose, owing to the fact that it provides an additional quota of calcium and phosphorus. In general the indirect rather than the direct method of therapy is preferable for nursing babies, because of the advantage to the mother as well as to the child. In the plan for the prevention of rickets, provision must be made for the nursing baby, for this disorder is by no means uncommon in the nursling. If mild "clinical rickets" is included, from one fourth to one third of all nursing infants manifest signs of this disorder.

Unless direct ultraviolet irradiation can be provided in an inexpensive and practical form combined with illumination, this method cannot be considered in the protection of the community at large from rickets. It is a valuable and effective measure and has value in the protection and cure of individuals, but at present it is limited in application owing to the fact that it requires the use of special apparatus.

---

[16] Hess, A. F.: Antirachitic Activity of Irradiated Cholesterol, Ergosterol and Allied Substances, J. A. M. A. 89: 337 (July 30) 1927.

We have confined ourselves in this discussion to the prevention of rickets in infants during the first and second years of life. It is becoming increasingly evident, however, that an antirachitic supplement is required throughout childhood, the period when there is not only marked growth in weight but in stature, in the growth and development of the bony skeleton. Whether antirachitic agents, such as activated food or ultraviolet radiation, are required for the best health and nutrition of the adult is a question which cannot be as yet satisfactorily answered.

There is another subject which, although somewhat afield, may well be mentioned in this connection; namely, the all important question of whether there is any cause for alarm in the rapidly increasing multiplication of foods which have been fortified with antirachitic vitamin. Antirachitic bread, vegetables and other foods have made their bow. It is true that the diet of children is lacking in this nutritional factor, but it may be asked whether this vitamin should be introduced at random and taken without medical advice and the knowledge or understanding of the parents. Incidentally, this raises the question, which we shall not discuss, of the desirability of adults partaking indiscriminately of foods rich in vitamin D. Besides the necessity for control of the potency of these products, which probably will be within therapeutic bounds unless some error occurs in the course of preparation, it may be questioned whether federal license and supervision should be required before such antirachitic foods are allowed to be marketed. This is a matter which is at present not under the jurisdiction of any bureau.

CONCLUSIONS

1. Pasteurized milk was activated by means of carbon arc rays, the radiant energy being carefully controlled and measured. It was found that sixteen seconds' exposure was sufficient to render the milk highly antirachitic.

A clinical test of this product in the prevention and cure of infantile rickets demonstrated that it is a highly effective antirachitic agent which can be relied on. Less than one quart daily sufficed to protect even Negro infants.

The great advantage of using activated milk, both fluid and dry, in the prophylaxis of rickets is that this measure furnishes an automatic method of therapy and likewise provides calcium and phosphorus.

2. Laboratory tests of this milk showed that it contained a comparatively small number of antirachitic units as judged by the standard rat assay. In view of the excellent clinical results, it is evident that the established method of assay cannot be relied on to appraise the value of irradiated milk for infants. This discrepancy in standardization was found also to hold true for tests of milk from cows which had been fed irradiated yeast ("yeast milk").

3. The indications for various antirachitic agents are discussed and appraised of (1) irradiated milk, fluid and dry, (2) "yeast milk," (3) cod liver oil, (4) viosterol, (5) irradiated yeast, (6) direct ultraviolet irradiation. Some of these measures are of value in the prevention and others for the cure of rickets, some for urban and others for rural communities. The use of irradiated fluid milk probably will be restricted to cities.

Clinical Notes, Suggestions and New Instruments

THE SAFETY NEEDLE

ROBERT J. LOWRIE, M.D., NEW YORK

During an operation the needle with which the surgeon sews may break, and even after a painstaking search the broken piece cannot always be recovered from the tissue. A needle may break in the most skilled hands. Nevertheless, the patient and relatives are not often ready to excuse the surgeon, and the latter may spend wakeful nights conjecturing what further trouble might be caused by the piece of steel left in the patient's body and whether he is to face a malpractice suit for alleged neglect.

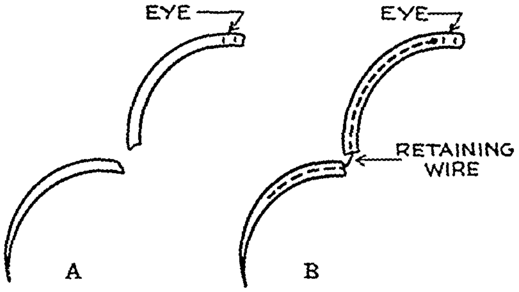

Fig. 1.—*A*, ordinary needle, broken; *B*, safety needle, broken.

Over a period of three years in the state of New York, there were at least fifteen claims brought against physicians because of fragments of broken needles being left behind after an operation. Even though the unfortunate physician is not "sued," his conscience bothers him and his reputation is liable to suffer.

In order to prevent the fragment of a broken needle from being lost in the tissue, I have designed a needle, which, if broken, controls or anchors the broken piece and so allows this to be readily and easily recovered from the tissue.

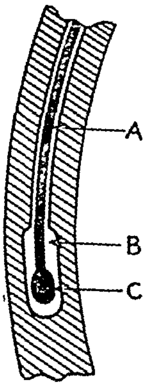

Fig. 2.—Enlarged section of safety needle, showing end of retaining wire in place: *A*, retaining wire; *B*, recess to allow play in retaining wire in case of bending or breaking of needle; *C*, enlarged end of retaining wire.

In figure 1 *A* is shown the ordinary surgical needle broken. The fragment with the point-end is completely detached and hence may "wander" afar in the flesh.

In figure 1 *B* is shown the safety needle broken, the fragments being held together by a retaining wire. The fine retaining wire *runs from the eye for not less than two* thirds of the length of the needle and is completely enclosed in a moisture-proof lumen or tunnel (fig. 2). Each end of the lumen is slightly enlarged to form a recess in which is confined the end of the wire, also enlarged by having its end turned back on itself. The retaining wire is not fastened to the walls of the lumen but may slide lengthwise for a distance of from 1 to 2 mm. This limitation of movement of the retaining wire is due to the inability of the enlarged ends to escape from the recesses into the lumen. Hence, when the needle breaks in the part containing the wire, the fragment of steel separates slightly (1 to 2 mm.) but is attached by the intact wire to the other part of the needle, which, of course, the surgeon controls.

A needle breaks at the point of greatest strain or leverage and this is usually where it is grasped by the needle holder.

On the first grasp, when the point of the needle is being forced through the tissue, the place of possible breakage is in the proximal half, usually a centimeter or two below the eye. If the break is below the surface of the tissue, the buried piece can be located by blunt dissection, the portion of the needle above the surface acting as a guide.

Occasionally when the needle holder is too close to, or right over, the eye, the break may be through the eye. As this is at the very end of the needle, only a tiny piece of metal is detached and quite often this can be located. But this type of break will not occur if the operator will keep the needle holder a half centimeter or so away from the eye.

The second grasp of the needle is in its distal third, near the point, when the other end of the suture is being drawn through the tissue. This portion of the needle does not contain the wire, but if the break occurs here the distal fragment is controlled by the needle holder and the proximal fragment is "tethered" to the suture. Therefore both fragments can be readily withdrawn from the tissue.

When the safety needle is used the following precautions should be observed:

1. The needle holder, when grasping the proximal end of the needle, should be at least 0.5 cm. away from the eye.
2. Make sure that the end of the short piece of suture is always at least 2 or 3 inches away from the eye, especially when the needle holder is on the point-end of the needle.
3. The needle holder should always be locked, especially when used on the point-end of the needle.
4. If the needle breaks, jerking, twisting or tugging should not be resorted to, but by blunt dissection, or cutting if necessary, the portion of the needle above the surface should be used as a guide to locate the buried fragment.
5. The safety needle should not be sterilized by boiling, but by immersion in alcohol, as in the case of scalpels and scissors.

Lumbar puncture needles and needles for giving clyses can have built in them the retaining wire, and so utilize the safety principle.

The safety device has thus far been employed in just one type of needle, the medium size, round needle. As time goes on the safety principle will be used in larger, or even smaller needles, either round or cutting.

In the early stages of development of the needle, I used for the "proving ground" a piece of tough beef, having deliberately broken several needles in order to note the usual point of breaking and also to get practice in recovering the fragment. Many of my colleagues have already used the safety needle and I have been using it for some time in my own private practice and in the ward cases.

The safety needle is identified by a small circle on the concave surface near the eye.

130 East Fifty-Sixth Street.

POISONING BY "EXLAX" TABLETS

Montague Cleeves, M.D., La Crescenta, Calif.

A healthy American boy, aged 10 years, ate the contents of a box of "Exlax" tablets in mistake for candy, March 26, 1932. He suffered severe purgation and his temperature rose to 106 F.; as household remedies failed to reduce this, the doctor was called the following evening. The only symptoms present were the temperature, 106, and a pulse of 130. The urine showed nothing abnormal. Fever persisted. On the 30th, a sudden eruption of huge wheals with sharply marked serpiginous borders appeared on the abdomen, legs and arms, disappearing the following day. Next day hemiplegia was apparent and the child became delirious. Multiple petechiae appeared on the abdomen and subcutaneous hemorrhages on the feet. A temperature of 103 persisted. Coma supervened, with gradual failure of respiration, and the child died at midnight, April 4, nine days after taking the "Exlax" tablets.

Necropsy showed a great number of hemorrhagic areas through the length of the intestine, varying in size from minute to several square centimeters, multiple minute hemorrhages in the kidneys, liver and brain substance, and marked congestion of the meninges (spinal puncture had shown a sterile lymphocytosis). The spleen was about four times the normal size and of mushy consistency, and was a very dark red. The heart walls showed multiple minute hemorrhagic areas and infarcts in the aortic valves (a few days before death a pronounced aortic murmur was audible); the suprarenal glands were almost liquefied.

The picture was one of a general destruction of the endothelium of the blood vessels, and the question arises whether a transfusion of blood might have been efficacious.

The active factor in "Exlax" is stated to be phenolphthalein. The literature reports occasional misadventures.[1]

INHALATION OF CARBON DIOXIDE IN THE PAROXYSMAL STAGE OF PERTUSSIS

Yandell Henderson, Ph.D., New Haven, Conn.
From the Laboratory of Applied Physiology, Yale University.

Inhalation of carbon dioxide, diluted in air or oxygen, is now established as an effective means of overcoming atelectasis and preventing pneumonia in the new-born, as well as for the reinflation of the lungs and prevention of pulmonary complications after anesthesia.

It seemed promising, therefore, to try a similar treatment in the paroxysmal stage of whooping cough. The object in this case is, however, not merely to forestall the risk of pneumonia but also to diminish the intensity and abbreviate the duration of the paroxysmal period. Pneumonia after pertussis probably comes from the obstruction of bronchi or bronchioles by mucus (Coryllos). The cough and whoop are due to irritation by adherent particles of mucus. Clearing the lungs by deep breathing should not only prevent pneumonia but also have the immediate advantage of diminishing the paroxysms of coughing. The object of this inhalation is, then, to keep the lungs sufficiently clear so that the paroxysms may be appreciably diminished in frequency and in intensity.

Experience shows that the inhalation of from 6 to 7 per cent carbon dioxide does not itself precipitate a paroxysm, as might perhaps have been expected. In some cases in which the child is uncooperative or resentful of any handling, a paroxysms may develop at the moment that the mask or hood is placed over the face. In these cases it is best, and indeed necessary, to delay the inhalation until that paroxysm is past; then it is recommenced and generally goes smoothly. The period of inhalation has been from ten to fifteen minutes either once or twice a day, preferably before a meal, or at least two hours after the last meal. The pulse is not considerably accelerated and breathing does not exceed that of a healthy child after a moderate amount of exercise. It is the depth rather than the rate that is increased. In this treatment, as in all uses of carbon dioxide, the percentage of the gas in the air, or oxygen, inhaled should be below the amount that would increase the rate of breathing or cause anxiety or strain in the patient. Under higher concentrations the depth of breathing may even decrease. Between 6 and 7 per cent mixed with air, or a mixture of 7 per cent carbon dioxide and 93 per cent oxygen, has been found to fulfil the requirements.

In some cases the mixture of carbon dioxide in oxygen has been administered by means of a mask and rubber bag. For this purpose the inhalator now commonly used by rescue crews for the treatment of cases of carbon monoxide poisoning is most convenient. Any one of the standard anesthesia machines affords the same conditions for the patient but they are more expensive. The portable infant inhalator now widely used for the resuscitation of the new-born from asphyxia or persistent atelectasis has also been found to be well adapted for this purpose.

In other cases, especially for children who objected to the mask, a small tent has been used having a capacity of about one cubic foot. Into the top of this tent a stream of carbon dioxide mixed with air is delivered through an injector. The gas comes from a cylinder of pure carbon dioxide to which are attached a reducing valve, a finely adjustable needle valve, and a manometer that blows off at a pressure of 8 inches water gage, this blow off preventing the possibility of excess. The injector in the top of the tent is adjustable to give a concentration of from 4 to 8 per cent carbon dioxide and a flow of more than 20 liters of the air and carbon dioxide mixture into the tent each minute This apparatus has been left in the home and used by the child's mother or nurse The cost of the gas is much less than when a mixture of carbon dioxide and oxygen is used, and the effects on the patient appear to be the same

[1] Phenolphthalein Poisoning with Analax Tablets, J. A. M. A. **98**: 340 (Jan. 23) 1932. McCarthy, F. P.: Dermatitis Medicamentosa (Phenolphthalein), Arch. Dermat. & Syph. **25**: 1142 (June) 1932.

This treatment has now been applied to ten children, ranging in ages from 9 months to 7 years All of them were suffering from frequent and distressing paroxysms of coughing In all cases after the third or fourth day of inhalation the paroxysms were considerably lessened in severity and frequency By the end of the eighth day coughing had become so infrequent that the inhalations were then discontinued

SCHULZ PAN DANDY BREAD
SCHULZ BAMBY BREAD (SLICED AND UNSLICED)

Manufacturer—Schulz Baking Company, Pottstown, Pa

Description—A white bread made by the sponge dough method (method described in THE JOURNAL, March 5, 1932, p 817), prepared from patent flour, water, malt extract, yeast, a yeast food containing calcium sulphate, ammonium chloride, sodium chloride, and potassium bromate, salt, sucrose, hydrogenated shortening and dry skim milk

Analysis (submitted by manufacturer)—

	per cent
Moisture (entire loaf)	34 2
Ash	1 7
Fat (ether extraction method)	0 8
Protein (N × 6 25)	10 3
Crude fiber	0 3
Carbohydrates other than crude fiber (by difference)	52 7

Calories—2 6 per gram 74 per ounce

Claims of Manufacturer—A bread of good quality

COMET BROWN RICE FLAKES
Flaked Genuine Brown Rice

(Flavored with malt, sugar and salt)

Manufacturer—Comet Rice Company, New York

Description—A flaked cooked and toasted brown rice containing added malt syrup, salt and sugar

Manufacture—Cleaned whole brown rice, malt syrup, salt and sugar are cooked under steam pressure for one hour in a revolving sealed cooker The cooked material is partially dried, flaked between steel rolls, toasted and packed in paper cartons

Analysis (submitted by manufacturer)—

	per cent
Moisture	4 4
Ash	2 5
Fat (ether extract)	0 9
Protein (N × 6 25)	8 4
Crude fiber	0 8
Carbohydrates other than crude fiber (by difference)	83 0

Calories—3 7 per gram, 105 per ounce

Claims of Manufacturer—A ready to eat brown rice cereal.

HARDY'S TWIN LOAF BREAD

Manufacturer—Hardy Baking Company, Flint, Mich

Description—A white bread made by the sponge dough method (method described in THE JOURNAL, March 5, 1932, p 817) prepared from patent flour, water, yeast, a yeast food containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate, salt, dextrose, lard, partially hydrolyzed starch and a mixture of calcium acid phosphate and calcium peroxide

Analysis (submitted by manufacturer)—

	per cent
Moisture (entire loaf)	36 8

REPORTS OF THE COMMITTEE

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT

RAYMOND HERTWIG, Secretary

CONDAY (GRAPE AND RASPBERRY FLAVORS)
Makes a Delicious Spread, Use in Place of Old Fashioned Jelly
NOT ACCEPTABLE

Thomson & Taylor Company of Chicago submitted to the Committee on Foods two products called Conday Grape Flavor" and 'Conday Raspberry Flavor ' The grape flavor product contains water, fruit pectin tartaric acid natural grape flavor, grape juice, potassium bicarbonate, dextrose, sucrose and artificial food color certified by the United States Department of Agriculture The raspberry flavor product is of essentially the same composition excepting that concentrated raspberry juice and natural raspberry flavor are the flavoring ingredients

Analysis (submitted by manufacturer)—

(Grape flavored)

	per cent
Moisture	91 2
Ash	0 3
Fat (ether extract)	0 2
Protein (N × 6 25)	0 2
Crude fiber	0 0

Crude fiber	0 0
Pectin	1 7
*Invert sugar (polarization method)	1 8
*Dextrose (polarization method)	1 2

* C A Browne, Sugar Analysis (1912)

Discussion of Label—A cursory reading of the label gives the impression that the article itself is the "delicious spread' mentioned Only after reading the rear label panel is the fact disclosed that a large quantity of sugar must be added and the "spread" prepared according to certain directions The prominent statement "Contains only pure fruit products" incorrectly implies that all the ingredients are derived from fruit This statement in conjunction with the facsimile of fruits including grapes, oranges, lemons and an unidentified fruit suggests the presence of the whole juice of the fruits, which is not correct The potassium bicarbonate, sucrose and dextrose ingredients are not derived from fruits The unqualified prominent statement "Use in place of old fashioned jelly" creates the unwarranted and misleading impression that the article is closely similar to what is popularly recognized as "old fashioned jelly "

In accordance with its published Rules and Regulations, the Committee recommended to the manufacturer that a descriptive statement naming the ingredients of the product be placed in proximity to the trade name Conday on the label and in advertising, the intent of the statement being to identify the article and to prevent possible deception or false implication that the product or the "spread" made from it is "true jelly" a generally recognized "all-fruit-juice sugar preparation"

The manufacturer was informed of the opinion and recommendations of t[illegible]Committee but has shown no indications of complying wit[illegible] the Committee's recommendations These products, therefore, cannot be listed among the Committee's "accepted" foods

CRYSTALLIZED FILTRABLE VIRUS

Possibly the reported successful crystallization of the etiologic factor of mosaic disease of tobacco may be regarded by future medical historians as one of the most important advances in infectious theory since the work of Lister and Pasteur. The announcement of the isolation of a crystallizable pathogenic enzyme necessarily throws doubt on the conception that poliomyelitis, smallpox and numerous other "ultramicroscopic infections" are of microbic causation. The apparent evidence that a specific protein, which in itself is incapable of self multiplication, may function as a disease germ when placed in "symbiosis" with normal cells seems to furnish experimental confirmation of several highly speculative theories relating to vitamins, hormones and progressive tissue degenerations.

The enzymic theory of the etiology of tobacco mosaic disease was suggested by Dr. A. F. Woods[1] more than thirty years ago. Since then the enzyme concept has remained the dominant working hypothesis in the experimental pathology of this and certain other plant diseases.

Subsequent extraction and preservation of the mosaic infectious agent by means of glycerin, the demonstration of its resistance to phenol, heat and ultraviolet rays, its precipitation by alcohol, acetone and other protein precipitants, its adsorption and subsequent elution from talc, and its partial isolation by electrodialysis have all been consistent with but not proof of its assumed enzyme character. Ten years ago, measurements of the diameter of this infectious colloid led Duggar and Armstrong[2] to the conclusion that each pathogenic unit is of the approximate size of a hemoglobin molecule. This is an order of magnitude similar to that subsequently demonstrated for "bacteriophage" and for numerous known plant and animal enzymes.

Recent studies of the hydrolytic products of this infectious colloid by Dr. C. G. Vinson and his co-workers[3] of the Boyce Thompson Institute for Plant Research, Yonkers, N. Y., have confirmed these observations and have led to the belief that the active component of the mosaic protein is a relatively simple atomic group, of which the infectious protein as a whole is a presumably necessary but relatively inert colloidal "carrier." This concept is in harmony with the accepted theory of known enzymes. From their relatively pure acetone precipitates from mosaic juice the New York plant pathologists finally succeeded in obtaining colloidal crystals, which were uniform in appearance and moderately infectious. They retained much of their infectivity on recrystallization. This decreased infective potential is in line with the progressively decreasing hydrolytic potential on recrystallization of known enzymes.

The essential problem before plant pathologists today is a determination of the ways in which such a pathogenic enzyme can initiate progressive enzymic perversion in living cells giving the appearance of enzymic self proliferation. This is similar to the essential problem of the new colloidal theory of "bacteriophage" and of numerous alleged "type transformations" in associated micro-organisms. An analogous problem is shown in the postulated quasiproliferating "pathogenic hormones" in certain progressive parenchymatous degenerations. These and numerous similar problems have already stimulated the speculative interest of biochemists. By a proper juggling with known chemical facts, Alexander[4] finds it logical to picture engrafted enzymic colloids functioning as "induced" or "modified genes" in "symbiosis" with living cells. The quasiproliferating "genetic perversion" causes atypical morphology and altered physiologic function. In extreme cases it may lead to the death of the perverted cell or of the multicellular host.

Clinicians must be prepared for the future endorsement of such metaphysical fantasies by medical investigators with the serious advocacy of their acceptability as working hypotheses in practical medicine.

PROTEINURIA IN YOUNG WOMEN

The appearance of protein in the urine of apparently healthy young persons has been the subject of much study and considerable conjecture. The Journal[1] has pointed out the importance of investigations of this problem from the point of view of the possible early recognition of renal disorder. The incidence of benign, non-nephritic, orthostatic, lordotic or postural albuminurias is about 5 per cent. This figure applies to young men only, and it varies somewhat depending on the method used in testing the urine. Among the etiologic factors involved in these cases of "physiologic proteinuria" it is well known that circulatory conditions are important. Thus, during strenuous exercise, which is known to provoke or aggravate proteinuria, the blood is largely diverted to the muscles and the skin. The kidney secretes little urine, which may contain albumin as the result, presumably, of local anoxemia rendering the glomerular endothelium permeable to the plasma proteins.

[1] Albuminuria in Young Men, editorial, J. A. M. A. **98:** 1470 (April 23) 1932.

Hellebrandt and her collaborators[2] at the University of Wisconsin have studied the relation of exercise to the excretion of protein by healthy young women. The subjects were physical education students and instructors ranging from 18 to 30 years of age. In forty-seven cases, seven, or 14.8 per cent, showed albuminuria. The urine samples were tested either with heat and acetic acid or with sulphosalicylic acid. Because these reactions are apparently more sensitive than the nitric acid ring test, it is probable that the demonstrated incidence of proteinuria in young women is about the same as that found by previous workers for men. Of the forty subjects whose urine was protein free, twenty-three, or somewhat over 50 per cent, showed some albuminuria after exercising in the gymnasium. A special study was therefore made in an attempt to correlate the effect of exercise on pulse pressure and on the presence or absence of protein in the urine. After riding the bicycle ergometer for thirty minutes, six subjects out of fourteen showed albuminuria. The average blood pressure of this group fell after exercise to 21 mm. below the preexercise level and did not return to normal until after seventy-two minutes. The eight subjects whose urine remained protein free showed a less marked drop in blood pressure, or 11 mm., and a return to normal in fifty-one minutes. Thus, the authors believe that the possibility of a sluggish circulation after exercise augments the local asphyxia of the kidney and contributes to the renal excretion of protein. Albuminuria was produced in those subjects who exhibited an excessive peripheral dilatation during exercise, as evidenced by flushing and sweating, and a deep and protracted fall in blood pressure after the cessation of exercise.

Further experiments indicate an interesting relationship between the speed of performing vigorous work and the quantitative excretion of protein. By means of a specially constructed bicycle ergometer with an electrodynamic brake it was possible to perform identical amounts of absolute work in a given length of time at speeds that could be varied within wide limits. Pedaling at the rate of 65 revolutions per minute and doing exhausting work for five minutes, five subjects eliminated an average of 4 mg. of protein per hundred cubic centimeters of urine. This is an almost protein-free secretion. Increasing the speed to 95 revolutions but maintaining the amount of external work constant in the same time period, these subjects showed an average excretion of 73 mg. of protein per hundred cubic centimeters of urine. The blood pressure rise during exercise and fall after its completion was nearly identical in the two experiments; hence it was not the important factor involved in the development of this proteinuria. It is known, however, that the amount of energy required to perform rapid work is more than for slower work, because of the increased frictional loss in the muscles, and the oxygen requirements are higher. The authors believe that their results may be explained on the hypothesis that violent exercise involving rapid movements brings about a generalized systemic increase in acidity. Should this condition alter the permeability of the glomeruli, protein might appear in the urine.

These experiments thus afford additional data relating the circulation with kidney function, and they offer interesting possibilities for future study. Though the significance of albuminuria in young adults still remains obscure, the contribution of the Wisconsin physiologists further elucidates some of the factors involved.

THE PREPOTENT FUNCTION OF THE SUPRARENALS

The great interest that has developed in the function of the suprarenal structures is thoroughly justified. The discovery of the indispensability of the suprarenals for life was, of itself, sufficient to promote the study of "these hitherto mysterious bodies." The demonstration that the cortex of the suprarenals is the part that has dominant importance for the body has diverted much of the investigation in this field away from the medullary part of the glands, which only a few years ago yielded the potent hormone epinephrine to science. Indications of the possibility of replacement therapy by means of suitable cortical extracts have acted as additional spurs to the laboratory workers in this field of endocrinology. To cap the climax, the growing evidences of the possible value of the cortical hormone in the management of that heretofore discouraging condition, Addison's disease, has awakened even the clinicians to the necessity of a vigorous study of suprarenal functions from every angle.

There is, indeed, danger that the pendulum of enthusiasm may momentarily swing too far in one direction, as so often happens when new discoveries are made. This is intimated in a recent paper in The Journal,[1] in which the following statements appeared:

> A limited amount of additional information has been gained during the eighty years since Addison first published his description of the disease which now bears his name, despite the production of a vast literature. One of the significant things, now apparently established, is that the essential patho-

[1] Harrop, G. A, Jr., and Weinstein, Albert: Addison's Disease Treated with Suprarenal Cortical Hormone (Swingle-Pfiffner), J. A. M. A. **98**: 1525 (April 30) 1932.

logic process in the disease lies in the cortical portion of the suprarenal gland and not in the medulla It is by no means proved, however, that direct or indirect impairment of function in the medulla is not responsible for certain of the characteristic clinical phenomena, particularly the pigmentation, the hypotension and the disturbance of sugar metabolism The predominant rôle of tuberculosis as the etiologic factor in about 80 per cent of the cases, and of a peculiar atrophy of the glands in nearly all the remainder, has also been established Finally, the remarkable tendency of the clinical course of the disease to remissions and relapses is now clearly evident

In reviewing the recent progress, Britton[2] has remarked that the development of a potent organ extract invariably signalizes an outburst of experimental work in the pertinent field, which is perhaps fortunate. Hope is thus engendered that suprarenal physiology may soon be stripped of much of its hazy theory and form a well founded part of the endocrinologic scheme The most recent contributions from Britton's laboratory[3] at the University of Virginia direct attention anew to the probable relations of suprarenals to carbohydrate metabolism The augmentation of blood urea, often referred to in cases of suprarenal deficiency, is not believed by the Virginia physiologists to be of primary significance but rather the expression of effects indirect or secondary to more fundamental changes Among these are the progressively severe reductions in the sugar content of the blood, and in liver and muscle glycogen stores, in animals deprived of their suprarenals Hence Britton and Silvette believe that the cortex is indispensably important in maintaining, in cooperation with other organs, the normal metabolism of carbohydrates in the body. The evidence indicates that this represents the principal function of the corticosuprarenal tissues The results appear significant, they add, in view of the severe myasthenic condition found in Addison's disease, and also in relation to the recently observed effects of corticosuprarenal extract in stimulating energy output. Administration of corticosuprarenal extract brings about recovery of animals which are in the terminal stages of insufficiency, apparently through initial restoration of normal carbohydrate values Increments in circulating sugar to the normal or even to hyperglycemic levels occur early after injection of the extract and are invariably associated with the disappearance of symptoms of insufficiency There are also correlated and striking *increases in liver glycogen* These conditions appear to be of primary importance in effecting recovery. Restoration is completed with the reestablishment of muscle glycogen values and the diminution of lactic acid in the blood That is why Britton and Silvette venture the conclusion that the cortical tissues and their hormones are primarily concerned (in conjunction admittedly with other secretions) in the maintenance of normal dextrose and glycogen levels in the body Since the cortex represents that part of the organs which is preeminently essential to life, the conclusion is derived that the regulation of carbohydrate metabolism may be considered as the prepotent function of the suprarenal glands

VITAMIN C—THE ANTISCORBUTIC VITAMIN

Ever since the discovery of the existence of vitamins as heretofore unrecognized dietary essentials, serious attention has been directed toward ascertaining the precise chemical nature of these indispensable food factors For a long time our knowledge was confined to an appreciation of the indisputable fact that many natural foods exhibit vitamin potencies and that the latter can be concentrated to a noteworthy extent by suitable biochemical procedures One outcome of such investigations has been the development of useful *vitamin concentrates of various sorts* It has become well established that the known vitamins cannot be produced de novo by the animal organism The latter is dependent, in ultimate analysis, on plants for the genesis of vitamins. Bacteria also apparently have some capacity to synthesize some of them In all these studies the research worker has been compelled to rely on tests with animals to ascertain the existence and potency of vitamins in the products studied, for the chemical structure of the effective agents remained unknown and consequently they could not be assayed by the method conventionally employed with most physiologically active substances of recognized make-up

Of late, progress toward the isolation and identification of some of the vitamins has been greatly accelerated[1] The discovery that the irradiation of a known substance, ergosterol, leads to the production of vitamin D, the antirachitic factor, was followed by the preparation of crystalline vitamin D Another significant discovery was the determination that one of nature's common yellow pigments, carotene, can serve as a precursor of vitamin A in the body Within the past year have come reports of the isolation or identification of vitamins A, B and C by Karrer or Drummond, Windaus and Rygh, respectively

According to Rygh and his co-workers,[2] the antiscorbutic vitamin can be produced from the long known alkaloid narcotine and is presumably so derived in nature. Unfortunately, the experimental results and conclusions of these Scandinavian investigators have failed of confirmation by a number of scientific workers both here and abroad.[3] Better success seems, however, to have attended the efforts of King and his associates[4] at the University of Pittsburgh. They venture to identify vitamin C with the hexuronic acid found by Szent-Györgyi in various plant tissues and in the suprarenal structures, as recently discussed in The Journal.[5] The Pittsburgh biochemists have isolated from orange juice a crystalline product that is protective to the conventional laboratory test animal, the guinea-pig, in daily doses of 0.5 mg. The details of the laborious undertaking need not be rehearsed here. If the claims are further substantiated, as now seems likely, a great step in advance will have been taken. In any event, further specific knowledge regarding the precise etiology and cure of scurvy cannot fail to result from these trends in research.

Current Comment

THE MEDICAL HISTORY OF SIR WALTER SCOTT

In recognition of the centenary of the death of Sir Walter Scott, famous as a master of graphic description, the *Edinburgh Medical Journal* recently issued a Scott centenary number. The issue includes several articles dealing with the medical aspects of the life of this famous novelist. Dr. Robert Hutchison[1] points out that Scott was one of twelve children, the first six of whom died in infancy, in that day not an uncommon occurrence, for dysentery and infection were frequent. Indeed, Walter Scott himself was being nursed by a tuberculous nurse, who chose to conceal the fact. She went privately to consult Dr. Black, professor of chemistry, who at once notified the father of Scott, so that the woman was dismissed and the infant consigned to a healthy peasant. When the child was 18 months old he suffered for three days with a fever which was thought to be the result of cutting large teeth. On the fourth day, when his nurse was about to bathe him, it was discovered that he had lost the power of his right leg. Many physicians were consulted without success; then the parents, eagerly grasping at every prospect of cure, tried every remedy suggested by any one. The condition was no doubt an attack of poliomyelitis, which left Scott lame for life. After all other remedies had failed, the child was sent to the country to live. There his general health improved greatly, although his affected limb was "much shrunk and contracted." Until the boy grew up, he was the subject of innumerable attempts to heal the paralyzed limb. Among others, the notorious charlatan Dr. James Graham, who has been described as the emperor of quacks, was called into the case, but his magnetic methods were of no avail. Scott triumphed over his paralysis by sheer grit and determination. Eventually, in spite of his limp, he could walk 30 miles a day and ride 100. At about 14 years of age he suffered from hemorrhages of the bowels, which unfortunately no one has been able to explain. At about 36 years of age he had an attack of gout and then at 46 repeated attacks of gallstone colic. Scott is described as a gargantuan eater. During the winter months he got little exercise and dined out much. His gallstone colic was treated with hot salt packs, profuse venesection and counterirritation. He says, "They bled and blistered till they left me neither skin nor blood." In fact, he describes his gallstone colic as "the cramp setting a fire to its lodging." After several years the attacks increased in their severity, being treated with large doses of laudanum, calomel and ipecac.[2] The writer was compelled to renounce beer and ale and also pastry, fruit and all that tends to acidity. In one attack lasting six hours he took 6 grains of opium, 3 of scopolamine and nearly 200 drops of laudanum. He also tried innumerable quack remedies without success. Finally, after a terrific dose of calomel, he seemed to recover from the acute condition and thereafter was troubled only with occasional twinges. In December, 1825, seven years before his death, he had a bad attack of renal colic. He died at the age of 62, following several attacks of cerebral hemorrhage. Outside of these diseases, his life was marred only by occasional spells of nervous exhaustion and rather rare attacks of what would ordinarily be called rheumatism. In his account of his own illnesses Scott describes with humorous skepticism the various remedies that were employed. Dr. David M. Greig[3] compares the life of Scott with that of another famous British author and poet, Lord Byron, who also was lame. Their careers are an indication of the way in which a physical defect may on occasion stimulate or be associated with cerebral activity leading to great fame.

EMBRYONIC SERUM COMPLEMENT

In many species of animals the embryonic blood does not contain demonstrable serum complement. Maugeri[1] of the Hygienic Institute, Berlin, could not detect complement in the serums of embryo rats or of embryo domestic swine. No trace of complement was demonstrable in the rat till the end of the first month of extra-uterine life. About two thirds of the adult complement titer was reached by the beginning of the third month. Maugeri quotes these data in support of the Friedberger theory that there is a definite ontogenetic cycle of serologic ripening in the young of many animal species, and presumably also in human beings. The low complement titers of premature infants suggests this cycle, even though the average full-term infantile titer is 80 per cent of that of the average maternal blood. Maugeri's demonstration of the relatively slow postnatal formation of serum complement in rats may well explain the rapidly increasing resistance of growing rats to pneumococci[2] and certain other infections. Many investigators have assumed that such an increase can result only from individual contact with the corresponding specific infectious agent or its reciprocal equivalent.

Association News

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts on Monday and Wednesday from 10:45 to 10:50 a. m. over Station WBBM (770 kilocycles, or 389.4 meters). The Columbia chain program has been discontinued for the present.

The subjects for the week are as follows:

August 22. Highways, Healthy Ways.
August 24. Infantile Paralysis.

There is also a fifteen minute talk sponsored by the Association on Saturday from 10:45 to 11 a. m. over Station WBBM.

The subject for the week is as follows:

August 27. Exercise for the Middle Aged.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

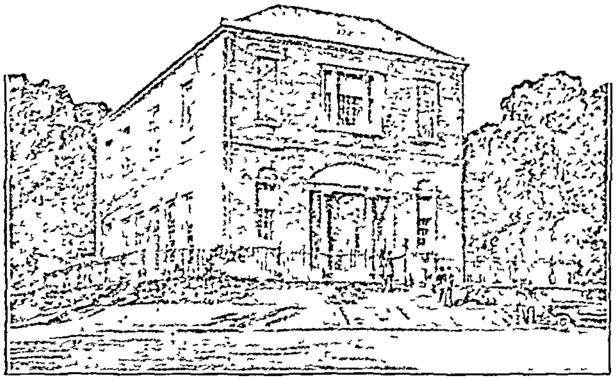
ARKANSAS

Personal.—Dr. Verdo T. Webb has been appointed health officer of Little Rock, succeeding Dr. Charles R. Moon, resigned.

License Restored.—The license of Dr. Joseph B. Story, Dierks, was restored, May 10, on his promise to refrain from advertising and on petition of the Howard County Medical Society. Dr. Story's license was revoked, May 12, 1931.

DELAWARE

Building Presented to Academy of Medicine.—The Academy of Medicine of Delaware dedicated a new home in Wilmington, June 1. It is a three story colonial structure, formerly occupied by the old National Bank of Delaware. Several small rooms and an auditorium, where meetings will be held, are located on the first floor. The second floor will be devoted to a library, private study and stack rooms. Third floor space will be used for club rooms. The Delaware Academy of Medicine was organized about three years ago, the state journal reports, with the establishment of a medical library as its primary purpose. It was incorporated under the laws of Delaware as a nonprofit organization to foster among its members interest in medical, social, economic and educational conditions, and to render service without recompense toward these ends in the state. Provision was made for young physicians to become affiliated at low dues, so that no reputable physician or dentist in the state would be denied its use. Presentation of the building was made by several persons in Wilmington. In addition to the gift of the building, it is the intention of these persons to furnish also the necessary equipment.



DISTRICT OF COLUMBIA

Health at Washington.—Telegraphic reports to the U. S. Department of Commerce from eighty-five cities with a total population of 37 million for the week ended August 6 indicate the highest mortality rate (14.7) appears for Washington and the rate for the group of cities as a whole, 8.9. The mortality rate for the corresponding week last year for Washington was 15.5, and for the group of cities, 10.4. The annual rate for eighty-five cities is 11.6 for the thirty-one weeks of 1932 as against a rate of 12.5 for the corresponding period of the previous year The department advises caution in the interpretation of these rates, as weekly figures fluctuate widely, as some cities are hospital centers for large areas surrounding them and as Negro death rates are usually high.

ILLINOIS

Personal. — Dr. William T. Short, Stonington, has been appointed district health superintendent of the state department of health, succeeding Dr. Frank P. Auld, Shelbyville. He will have charge of the counties of Macon, Christian, Fayette, Shelby, Cumberland and Montgomery.

Diphtheria Wanes in Illinois.—According to the *Illinois Health Messenger,* case reports of diphtheria for the first twenty-nine weeks of 1932 indicated a decline of 31 per cent as compared with the total for the corresponding period of 1931. In the first five months of 1932 there were 112 deaths from diphtheria against 184 in that period of 1931, a decline of nearly 40 per cent. Cases reported during the six weeks ended July 18 were less than one half the number for the similar period of 1931, which was one of the most favorable years on record Credit for the decrease in diphtheria is given to the successful diphtheria immunization campaigns carried on throughout the state. Never before have so many children in Illinois been immunized against the disease as during the last twelve months, the *Health Messenger* reports.

Chicago

School for "Occupation Therapy."—Plans are under way for the establishment of a school for occupation therapy to work in connection with the Goodwill Industries' shops for the handicapped and occupation service, and the Cook County Hospital. The organization meeting was held, July 27. Work is being directed to have the school in operation by early fall. The school will be housed in the headquarters of the Goodwill Industries, which is now located in the building formerly occupied by the University of Illinois College of Medicine and which was turned over to the industries in recognition of its work for the rehabilitation of the handicapped. The school is to be independent from all existing medical institutions so as to be able to serve all of them equally well, an announcement states. It is intended to offer free demonstration courses to medical students and physicians. Intensive courses of two, three or four years, to train technicians and practitioners of occupational therapy, may be developed on the basis of the lowest possible student fee to render this nonprofit enterprise self-sustaining in the course of time, the announcement continues. The board of trustees, when organized, will devise some plan of providing a budget. The Goodwill Industries are organized for philanthropic purposes, and the primary objective is to provide occupational training for the handicapped.

INDIANA

Assumes Deceased Physician's Identity.—The arrest of a Negro, whose name is believed to be R. L. Combs, and the revocation of a license by which he was practicing medicine was recently reported by the Indiana state board. The American Medical Association, Feb. 12, 1931, received information from a Dr. William T. Thomas indicating that he was practicing at 2105 Broadway, Gary; that he was a graduate of the Louisville National Medical College in 1897, and that he was licensed in Indiana in the same year. Subsequent checking of the records disclosed that a physician with this name and record was reported to have died at Marion, Sept. 6, 1924, of heart disease. The Indiana State Board of Medical Registration and Examination found out that "Combs" several months ago called on Mrs. Ileene Thomas Burden, stating that he was a representative of the state of Kentucky. He said that he was prepared to secure for her a monthly pension of $75 if she would furnish the diploma and license of her father, Dr. William T. Thomas, who died in Marion in 1924. Mrs. Burden testified at the recent hearing before the state medical board that she identified the man who is practicing medicine at 2105 Broadway as the same man who obtained from her the diploma belonging to her father. The Grant County license, obtained by the method described, was presented to the Lake County clerk, June 12, 1928, and a new license was issued. The board of medical registration has revoked this license and will proceed to prosecute "Combs" should he continue to "practice" in Indiana. It is reported that he is now charged by the federal government with obtaining a narcotic permit by fraud.

LOUISIANA

New District Medical Society.—Dr. Daniel N. Silverman, New Orleans, councilor of the newly organized Second Congressional District Medical Society, presented a charter to the society at a meeting in Destrehan, July 22. By-laws were adopted by the society, and it was decided to hold regular monthly meetings the third Thursday in each month. Dr. Lionel O. Waguespack, secretary, gave a talk on the purposes of the new society. Other speakers included Drs. Roy B. Harrison and Paul T. Talbot, New Orleans, president and secretary, respectively, of the state medical society; Dr. Hector E. Bernadas, chairman of the council of the state society, and Dr. Leon J. Menville, New Orleans, president of the state board of medical examiners.

Alleged Violation of Milk Ordinance.—A recent investigation by the board of health of New Orleans resulted in the filing of eighty-three affidavits in recorders' courts, July 24, against dairymen "for alleged violation of the city ordinance prohibiting the sale of milk adulterated with dried milk powder." These dairymen have been selling the "powdered" milk for pure milk and charging usual prices, newspapers stated. It was pointed out that salesmen distributed the powder to the dairymen, giving them detailed instructions how to mix it so that the adulteration could not be detected. The dairyman could buy four pounds of powder at about 9 cents a pound. This could be made into ten gallons of "milk," which would be mixed with twenty gallons of pure milk, newspapers reported.

MARYLAND

Outbreak of Food Poisoning.—Eating custard-filled doughnuts caused the illness of twenty-nine people in Baltimore early in July. An investigation by the city health department revealed the fact that the doughnuts were made at one bakery and then placed on sale at a number of grocery stores. The process of manufacture was such that the custard filling was probably allowed to remain unprotected and unchilled from the time it was prepared until the final filling procedure and sale, Baltimore *Health News* states. It was said that the warning which had been issued to the baking industry of the city last year by the bureau of chemistry and food had not been heeded in this instance.

MICHIGAN

State Medical Meeting at Kalamazoo.—The one hundred and twelfth annual meeting of the Michigan State Medical Society will be held in Kalamazoo, September 13-15, under the presidency of Dr. Carl F. Moll, Flint. Meetings will be held at the First Presbyterian Church and the Civic Auditorium. As a departure in the program this year, the individual sections will convene in the mornings, and in the afternoons will join in combined meetings. The preliminary program includes the following speakers with their subjects:

Dr. Howard J. Parkhurst, Toledo, "Physical Therapy of the Commoner Skin Diseases"
Dr. George F. Suker, Chicago, "Retinal Lesions Encountered in Cardiovascular Disease."
Dr. Millard F. Arbuckle, St. Louis, "Factors in Making the Diagnosis in Sinus Disease."
Dr. Walter I. Lillie, Rochester, Minn., "Clinical Significance of Retrobulbar Neuritis."
Dr. Warren T. Vaughan, Richmond, Va., "Certain Rhinologic Aspects of Allergy."
Dr. Stuart W. Harrington, Rochester, Minn., "Empyema."
Dr. Samuel A. Levine, Boston, "Treatment of Acute Coronary Thrombosis."
Dr. Joseph L. Miller, Chicago, "Arthritis"
Dr. Christopher M. Spooner, Toronto, Ontario, "Anomalies of the Genito-Urinary Tract in Children."
Dr. Francis E. Senear, Chicago, "Infantile Eczema."
Dr. Arthur U. Desjardins, Rochester, Minn., "Therapeutic Radiology in Relation to Infancy and Childhood."
Dr. Frederick H. Falls, Chicago, "Diagnosis and Management of Premature Detachment of Normally Implanted Placenta."
Dr. Eric M. Matsner, New York, "Methods Employed in Birth Control."
Dr. Joel E. Goldthwait, Boston, "Posture."

Dr. Edward H. Cary, Dallas, Texas, president, and Dr. Olin West, Chicago, secretary and general manager, American Medical Association, will speak. Dr. Morris Fishbein, editor of THE JOURNAL, Chicago, will address the second general meeting, Thursday evening, September 14, on "The Community's Responsibility to the Medical Profession." In addition to the out-of-state guests, an elaborate program will be presented by Michigan physicians. Round table conferences will be held and moving pictures shown.

MINNESOTA

Violates Basic Science Law.—James J. Carrigan, St. Paul, pleaded guilty, July 19, to a charge of practicing healing without a basic science certificate, before Judge Loevinger of the district court. The defendant, who claims to be a chiropractor and a naturopath, and who formerly practiced in Alberta, Canada, attempted to treat a woman afflicted with a nervous disorder. In addition to giving the patient massage treatments, he sold her a magna-coil electric blanket for $100 and a rupture appliance for $12. He had no medical education whatever and stated in court that he left school at the age of 16. Carrigan was sentenced to ninety days in the St. Paul workhouse. The sentence was stayed for one year and the defendant placed on probation on condition that he refrain from practicing and selling any devices or remedies for the curing of ailments. He was required to return the $12 received from the sale of the appliance.

MISSISSIPPI

Courses in Obstetrics.—Dr. Felix J. Underwood, Jackson, announces that four additional courses in obstetrics for physicians will be given by Dr. James R. McCord, professor of obstetrics and gynecology, Emory University School of Medicine, through an arrangement of the state board of health with the federal children's bureau. A course will be given one week in October, one in November and two weeks in December. Dr. McCord has already given courses of lectures at Indianola, New Albany, Vicksburg, Laurel, Houston, Brookhaven, Jackson, Meridian and Gulfport.

Society News.—At the meeting of the Issaquena-Sharkey-Warren Counties Medical Society, July 12, speakers included Drs. Winston C. Pool, Cary, on "Congenital Syphilis," and Henry B. Goodman, Vicksburg, "Sodium Amytal in the Treatment of Eclampsia." The program, June 14, was given by Drs. Willard H. Parsons on appendicitis; Nathan B. Lewis, the need for anesthetics during labor, and Guy P. Sanderson, Vicksburg, pyelitis.——The East Mississippi Medical Society was addressed, June 16, by Drs. Willis Walley, Jackson, on "Carcinoma, Its Treatment with Special Reference to the Use of Deep X-Ray Therapy," and James L. Parkes, Union, "Tularemia." Hon. Marion W. Reily, Meridian, discussed "The Doctor in the Court Room."——Dr. William F. Hand, Jackson, spoke on "Sarcoma of the Pancreas" before the Central Medical Society at Jackson, June 21.——"The Fracture Problem" was discussed by Dr. Willis C. Campbell, Memphis, Tenn., before the Pike County Medical Society, July 7.——At a meeting of the South Mississippi Medical Society in Hattiesburg, June 9, speakers included Drs. Roland H. Cranford, Laurel, on "The Cancer Situation in Mississippi"; William A. Dearman, Gulfport, "Infectious Mononucleosis," and Theophilus E. Ross, Jr., Hattiesburg, "Treatment of Normal Breech Presentation."

MISSOURI

Personal.—Dr. Malcolm A. Bliss, St. Louis, was presented, June 24, with the "distinguished service medal" for conspicuous service in private life, the first to receive the medal since it was authorized by the last legislature. The presentation was made by Governor Caulfield in the state senate chamber, with prominent physicians and members of the state eleemosynary board in attendance.

Graduate Meeting.—The Five County Medical Society of Southeast Missouri held its second quarterly graduate session at New Madrid, June 14. Lecturers and their subjects were Drs. Joseph P. Costello, "Treatment of Some Common Acute Conditions of Infants and Children"; Harry G. Bristow, "Diagnosis and Treatment of Some Acute Infections," and Alphonse McMahon, "The Endocrines." All the speakers were from St. Louis. The next meeting of the Five County Society will be the second Tuesday in September, with the Dunklin County Medical Society acting as host.

Low Diphtheria Death Rate.—The lowest number of deaths from diphtheria ever recorded in St. Louis was noted for the year *1931*. The rate was 4.5 for each hundred thousand of population Credit for the decrease in the disease is given to the campaign conducted during 1931 by the health departments and medical societies of St. Louis and St Louis County A marked advance in the mortality from tuberculosis was noted There were 878 deaths, a rate of 105 9 per hundred thousand, the highest rate in seven years and an increase of 21 per cent over 1930 This is the greatest increase of any city in the country, the journal of the state medical association reported

NEW HAMPSHIRE

Physicians Honored by State Society—At the recent annual meeting of the New Hampshire Medical Society in Manchester, gold medals marking the completion of fifty years' membership in the society were presented to Drs Herbert S Hutchinson, Milford, and George Weare Weymouth, Lyme. Tribute was paid also to three other physicians who had practiced fifty years, although they had not held membership for that period Drs Leonard Jarvis, Claremont Ira Joslin Prouty, Keene, and Edward H French, Quincy Mass Dr French was formerly connected with the New Hampshire State Hospital, Concord Newspapers have reported that Dr Prouty died, July 31.

NEW JERSEY

Examination of Domestic Employees.—Results of the first fifteen months' operation of an ordinance requiring physical examination of domestic employees in Newark are reported by the city health officer in *Public Health News* During 1931, when the law was not generally known to the public, 2 863 persons were examined More definite efforts toward enforcement in the first three months of 1932 brought about 3 136 examinations As a result of clinical examinations and a check up of domestics attending venereal disease clinics, eighty persons were found infected with syphilis in some form, thirty-eight had skin diseases and thirty-one had tuberculosis Those who have arrested cases of tuberculosis or venereal disease in a noncommunicable form are allowed to continue in employment but those who may communicate a disease are refused permission to continue The department follows up all applicants found to be infected to see that proper treatment is carried out The nature of the disease is not divulged to the employer

Centenary of Trenton Board of Health—An ordinance creating a board of health in Trenton, dated July 3, 1832 has recently been found by the city clerk This was fifty-five years before local boards of health were required by law in New Jersey The board appears not to have been appointed for a definite length of time, but one could be appointed in case of need and it could dissolve itself when its work was done Among the names of members of the first board were Drs James T Clark, John McKalway, Peter Howell, Joseph C Welling and Francis A Ewing The board was authorized to procure and circulate advice concerning the danger of infectious and contagious diseases and in time of epidemic to "take such measures as they may deem best calculated to arrest its progress and render its ravages less destructive," and it was its duty to "make daily reports of progress of the disease and the measures which they have adopted' The first part of the ordinance outlined a procedure for keeping streets and public grounds clean, inhabitants were required to clean their pavements each week from May to October and were liable to fines of $25 if they omitted this task

NEW YORK

Dr. Goler Retires—Dr George W. Goler, health officer of Rochester since 1896, retired from that office, July 31 He plans to continue as lecturer in preventive medicine at the University of Rochester School of Medicine and Dentistry and to finish writing a history of medicine in Rochester during the past fifty years Dr Arthur M Johnson, deputy health officer for eight years, succeeded Dr Goler

New York City

Dr. Park Receives Medal—The National Academy of Sciences announces that its public welfare medal for eminence in the application of science to the public welfare is to be awarded to Dr William Hallock Park, director of research laboratories of the New York City Department of Health The citation refers to Dr Park's work as a pioneer and leader both in research and in the application of scientific discovery in the prevention of disease The medal will be presented at the next annual meeting of the academy at Washington, D C, in April, 1933 Ten previous awards have been made, as follows the late Gen George W Goethals, 1914, the late Dr William C Gorgas, 1914, Cleveland Abbe, Ithaca, N Y, geographer, 1916, Gifford Pinchot, present governor of Pennsylvania, 1916; Samuel W Stratton, late president of Massachusetts Institute of Technology, 1917, President Hoover, 1920; Dr Charles W Stiles, Washington, 1921, Dr Charles V Chapin, Providence, R I, 1928; the late Stephen T Mather, 1930, and Wickliffe Rose, former president of the General Education Board New York, 1931 This award was established in 1913 through a gift from Mrs Helen Hartley Jenkins, in memory of her father, Marcellus Hartley.

Lying-In Hospital Moves to Medical Center.—The last patients left the Lying-In Hospital, Second Avenue and Seventeenth Street August 7, as final preparations were made to close the institution which becomes a part of the women's hospital of the New York Hospital-Cornell University Medical Center when it opens, September 1 Lying-In Hospital, founded in 1798 was said to be the oldest maternity hospital in the city The Lying-In Society, which operated it, was founded especially to care for the widows of men who died in a yellow fever epidemic at that time, according to an account in the New York *Herald Tribune* First established at a house on Cedar Street, the hospital has occupied various sites From 1801 to 1827 its income was used simply to maintain a ward in the New York Hospital For many years afterward the society operated a district service for mothers in their own homes In 1895 with the aid of the late J Pierpont Morgan, a hospital for forty patients was established in the old Hamilton Fish mansion in Stuyvesant Square, with Dr William H. Spiller, present medical superintendent, as resident physician This building was closed in 1899 and there was no hospital in operation until January, 1902 when the building just vacated was opened It is reported that this building will now be taken over by Gramercy Hospital, formerly the New York Skin and Cancer Hospital

OHIO

District Meetings—The Seventh District Medical Society held its annual meeting, June 17, at the Union Country Club, Dover Speakers on the scientific program were Drs Isaac B Harris Columbus on 'Acute Obstruction", Charles J Shepard, Columbus, 'Treatment of Prevalent Skin Diseases', Wells Teachnor, Columbus, 'Injection Treatment of Internal Hemorrhoids ' Drs Herbert M Platter, Columbus president of the Ohio State Medical Association, and Emmet B Shanley, New Philadelphia, councilor of the seventh district, also made addresses ——The annual meeting of the Eighth District Medical Society was held, June 23, at the Rocky Glen Sanatorium, McConnelsville Among the speakers were Drs Charles A Doan and Ray W Kissane, Columbus, on 'The Basis of Prognosis in Disease and "Habits in Heart Disease," respectively. Dr Herbert M Platter, Columbus, president of the state medical association, and Dr Harry G Southard Marysville, state health director, were among the speakers at a luncheon meeting

PENNSYLVANIA

Society News—The medical societies of Clearfield, Jefferson and Indiana counties held their third joint meeting, August 11, at Indiana with the following speakers Drs Edward B Heckel, Pittsburgh, "Injuries to the Eyeball , Donald Guthrie, Sayre, 'Symptomatology and Early Diagnosis of Intestinal Obstruction", Ronald L Hamilton Sayre, "Electrocardiography as an Aid in Diagnosis of Heart Disease." Dr Hugh Robertson, York, showed a motion picture film of an electrocardiogram during angina pectoris ——The Cambria County Medical Society held its annual "north of the county" meeting at the Chetremon Country Club near Cherry Tree, August 11, with Dr William S Wheeling, Windber, as the speaker, on disease of the thyroid The society will hold its annual picnic, September 8, at the Johnstown Rod and Gun Club.

Philadelphia

University News—A clinic for prenatal and postnatal care to needy mothers was opened, August 5 at the Germantown Community Center, under the auspices of the Woman's Medical College of Pennsylvania Dr Ann G Taylor, clinical professor of obstetrics, is in charge

Health Department Requests Serum—Dr J Norman Henry, director of public health, is reported to have issued a call for donations of blood serum from persons who have had infantile paralysis, to meet the need in current cases It was said that forty cases had been reported in the city between August 1 and 8 In 1931 there were only fourteen cases in the whole month of August

Hospital News.—Garretson Hospital, the maternity hospital of Temple University School of Medicine, is to be removed to a new addition to the Temple Hospital, it has been announced ——An artificial respirator has been presented to Northeastern Hospital, in memory of the late Dr John H Lock, by Dr and Mrs Frederick E Keller, his son-in-law and daughter ——Dr Joseph C Bloodgood, Baltimore, gave an address at Jeanes Hospital, August 2, on cancer

TENNESSEE

Hospital News. — A $325,000 building has recently been completed at the Western State Hospital, Bolivar, for the care of insane Negro patients It has accommodations for 400 patients, including two wards for the tuberculous —— Martha Gaston Hospital, occupying the building formerly known as the Cedarcroft Hospital newly renovated, was opened, August 15 Dr Robert B Gaston, owner and superintendent of the new hospital, was formerly superintendent of McFarland Hospital, Lebanon, which will now be operated with Dr Jerry J McFarland in charge

Society News. — Drs Hugh F Crawford and Giles A Coors, Memphis, addressed the Memphis and Shelby County Medical Society recently on "Undulant Fever" and "Postoperative Gangrenous Ulcer of the Abdominal Wall," respectively ——Dr. Julius C Brooks addressed the Hamilton County Medical Society, August 11, on "History of the Medical Profession in Chattanooga," and Dr Fred B Stapp, "Looking Backward"——At the June 28 meeting of the Knox County Medical Society, Dr Richard A Barr, Nashville, spoke on "Preoperative and Postoperative Treatment of Abdominal Cases"——Dr Paul B Welch, Coral Gables, Fla, delivered a lecture before the Sullivan-Johnson Counties Medical Society, Bristol, August 3, on gastro-intestinal reflexes ——Drs Rudolph W Holmes, Chicago, and Frederick C Freed, New York, addressed the Gibson County Medical Society, Trenton, July 25, on obstetrics

WISCONSIN

License Revoked—The license of Dr Leland L Trump, Milwaukee, was revoked by the state board of registration June 29, on the reading of his court record of conviction of manslaughter

Society News—At a meeting of the fifth district of the Wisconsin State Medical Society at Kiel, July 28, speakers were Drs Philip W Brown, Rochester, Minn, on colitis, Kellogg Speed, Chicago, fractures, and Herman C Schumm, Milwaukee, uses and application of plaster of paris Dr William A Evans, Chicago, spoke in the evening on "What's Happening to Doctors"——Three physicians addressed the Racine County Medical Society, Racine, June 16, as follows Drs Walter H Watterson, La Grange, Ill, and Stanton K Livingston, Hines, Ill, on artificial pneumothorax and maggot treatment of osteomyelitis, and Willard Van Hazel, Chicago, thoracoplasty ——Dr Samuel R Mitchell won the first low gross score and Dr Benjamin E Urdan the first low net score at the fifth annual golf tournament sponsored by the Milwaukee County Physicians' Golf Association and the Milwaukee County Medical Society, July 21, at the Waukesha Country Club

WYOMING

State Medical Meeting and Election.—Dr Herbert L Harvey, Casper, was named president-elect of the Wyoming State Medical Society at the annual meeting in Rock Springs, July 18-19 Dr. Frederick L Beck, Cheyenne, was installed as president, Dr Joseph L Wicks, Evanston, was elected vice president, and Drs Edwin Earl Whedon, Sheridan, and Ewald Olson, Meeteetse, were reelected secretary and treasurer, respectively The 1933 annual meeting will be held in Yellowstone Park At the first session the president, Dr Robert H Sanders, Rock Springs, made his annual address and Dr Edward H Cary, Dallas, Texas, President, American Medical Association, gave an address Dr Cary also contributed to the scientific program an address on glaucoma Among other speakers were Drs Foster J Curtis, Salt Lake City, "Raynaud's Disease Differential Diagnosis", William P. Wherry, Omaha, "Sinus as a Source of Infection", Warren Thompson, Omaha, "Blood Dyscrasias", Karl S J. Hohlen, Lincoln, past president, Nebraska State Medical Association, "Modern Phases of Traumatic Epilepsy", Richard A Pearse, Brigham City, Utah, president, Utah State Medical Association, "Tularemia", G Gill Richards, Salt Lake City, "Medical Management of Gastric Ulcers," and Frank B Stephenson, Denver, president-elect, Colorado State Medical Society, "Bone Tumors Roentgenologically Considered" Clinics were held each morning at the Wyoming General Hospital The Sweetwater Medical Society entertained with the annual banquet and dance, Monday evening, July 18

GENERAL

American Hospital Association in Detroit.—The thirty-fourth annual session of the American Hospital Association will be held in Detroit, September 12-16, under the presidency of Mr Paul H Fesler, superintendent, Wesley Memorial Hospital, Chicago Among numerous physicians who will take part in the program are Drs Joseph C. Doane, Philadelphia, who will lead a round table discussion on financial problems of hospitals Fred G Carter, St Paul Minn, who will speak on 'A Medical Approach to Hospital Administrative Problems", Edward J O Brien, Detroit, "Surgical Treatment of Pulmonary Tuberculosis', Henry D Chadwick, Detroit, "The Tuberculosis Problem as It Affects the General Hospital" and Malcolm T MacEachern, Chicago, who will lead round table discussions, among other things, on making greater use of existing hospital facilities, including their use for veterans

American Academy of Ophthalmology and Otolaryngology—The thirty-seventh annual meeting of the American Academy of Ophthalmology and Otolaryngology will be held in Montreal, Canada, September 19-23 Dr Samuel Hanford McKee Montreal, is president and Dr Burt R Shurly, Detroit, president-elect The opening session will be devoted to a symposium on the progress of general medicine in relation to diseases of the eye, ear, nose and throat Thereafter the mornings will be occupied with demonstrations under sixty-five instructors Four special courses will be given "Histopathology of the Eye' 'Histopathology of the Nose, Throat and Ear," "Lesions of the Fundus' and 'Clinical Pathology of Otitic Lesions" Section meetings will be held in the afternoons The American Board of Otolaryngology will conduct examinations Saturday, September 17, and the American Board of Ophthalmic Examinations will hold examinations, Monday, September 19

Prevalence of Typhoid—Newspapers reported nine cases of typhoid recently in Carthage, N Y, among which two deaths occurred The cases were attributed to a hitherto unknown carrier who was found to have handled the milk supply used by all the patients Dr Arthur T McCormack, Louisville, health officer of Kentucky, warned of a serious epidemic in that state, 603 cases having been reported in July, compared with 105 in July, 1931 Ten cases were reported, July 13, in Hocking County, Ohio, eight of which were in one community, seven cases, including six in children, were being investigated in Athens County Still another outbreak, in Muskingum County, was attributed to swimming in polluted streams Five cases in Newkirk, Okla, caused the state health department to begin an investigation to trace the source of the infection Sixty cases occurred in the state during the week ended July 23, according to the health department The U S Public Health Service announced that 1,231 cases had been reported from forty-six states during the week ended July 23

Survey of Facilities for Lepers—A survey to determine the adequacy of facilities and the extent to which provisions are made for the protection of the public health in the care and treatment of leprous persons in Hawaii has been authorized by a joint resolution of Congress The resolution was based on information furnished by the governor of Hawaii to the effect that there are at the present time 623 patients being cared for at the expense of the territory in its leprosariums The cost entailed in this care is considered a heavy burden on the "limited resources of the territory" Physicians of the U S Public Health Service who will conduct the survey are Drs, James C Perry, John W Kerr and George W McCoy They will prepare an estimate of the cost of construction and equipment of a receiving station and hospital, including the purchase of necessary grounds as well as an estimate of the annual cost of maintenance and operation They will also report on remedial legislation providing for the further control and eradication of the disease in the territory In 1905, a congressional appropriation provided for the establishment of a hospital station and laboratory of the Public Health and Marine Hospital Service of the United States for the study of the methods of transmission, cause and treatment of leprosy at Kalawao, Island of Molokai About 640 acres was transferred in perpetuity to the United States by the territory However, after several years' operation, it was found impracticable for the United States to maintain a separate institution, and through subsequent legislation the land was reconveyed to the territory Except for a station at Kalihi receiving hospital, Honolulu, the territory has since then borne the complete expense of caring for leprous persons in its jurisdiction. None of the territory leper patients have ever been cared for in the leper colony at Carville, La., the establishment of which was provided for by an act of Congress in 1917. The Kalihi station, known as the U. S. Leprosy Investigation Station, is administered by the public health service.

FOREIGN

Typhoid Outbreak in Havana.—Five deaths and thirty-two cases of typhoid were reported in Havana, Cuba, within twenty-four hours in a serious outbreak, the Chicago *Tribune* reported July 27.

Cholera in China.—Newspapers reported, August 2, that cholera was widespread in southern Hupeh. So serious was the spread of the disease in western Honan province, it was stated, that authorities appealed to Nanking for medical assistance. The death rate in the city of Honanfu was mounting rapidly. Bubonic plague was also taking a heavy toll in lives, the report continued. The flooding Canton River demolished 600 houses and drowned 500 persons at Canton proper, it was said. In a home for the aged, which was submerged, eighty persons perished. According to the report, in western Shensi province the Yellow River had inundated thirty towns, leaving 50,000 persons homeless.

Typhus Fever Epidemic.—*Public Health Reports* records a recent epidemic of typhus fever in the Vilna district of Poland. The disease was prevalent in the county of Dzisna and had broken out in the county of Molodeczno, where twenty-three new cases had been reported. Preventive measures had been successful in the counties of Braslaw, Swieciany and Oszmiana, where only six cases had been reported. In Wolozyn County, 150 new cases, with 20 deaths, were recorded. This county was said to be the central point in the epidemic. The disease was prevalent in the districts of Soviet Russia bordering on Molodeczno County, it was said. The Polish public health service reported 106 cases of typhus fever for the period May 8-14, 1932.

Government Services

Army Personals

Major Bartlett L. Shellhorn, relieved at Watertown Arsenal, Massachusetts, and assigned to duty at Fort George Wright, Washington; Major Arthur D. Jackson, relieved at Fort George Wright and assigned to Fort Wadsworth, N. Y.; Lieut. Col. James A. Wilson, assigned at Fort Snelling, Minnesota, effective on completion of present tour of foreign service; Lieut. William A. D. Woolgar, relieved at Fort Lewis, Washington, for assignment to duty in China; Major Thomas L. Long, relieved at San Francisco and assigned to duty in Hawaiian Department; Majors Robert L. Tebbitt and Rae E. Houke, having been found incapacitated for active service on account of disability incident thereto, and such finding having been approved by the President, their retirement is announced; Lieut. Col. Harry H. Van Kirk, Columbus, Ohio, proceeded to his home about June 16 to await retirement for the convenience of the government.

U. S. Public Health Service

P. A. Surg. Edward R. Pelikan, relieved at Manila, P. I., June 18 and assigned to duty at Angel Island Quarantine, Calif.; Surg. William F. Tanner, relieved at Rosebank, S. I., N. Y., and assigned at U. S. Quarantine, Brownsville, Texas, to assume charge of service activities; A. A. Surg. Frank D. McCreary, relieved at Evansville, Ind., and assigned to duty at Carville, La.

Course for Reserve Officers

The fourth medicomilitary course of inactive duty training at the Mayo Clinic, Rochester, Minn., for Medical Department Reserve Officers will be held October 16-29. All the facilities of the clinic are placed at the disposal of the officer students and the faculty and staff have volunteered their services in the interest of national defense. Morning hours will be devoted to purely professional subjects selected by the students, afternoons to medicomilitary subjects, and evenings to a lyceum course of general interest, according to the announcement. Application for the course should be made to the director of the Mayo Foundation, Rochester, Minn., or to the Corps Area Surgeon, Seventh Corps Area, Omaha, Neb.

The New Edition of the British Pharmacopeia

The new edition of the British pharmacopeia is larger than the edition of 1914, containing 763 pages against 633, and several important changes have been made. A new feature is the addition after the doses of the important drugs of notes for prescribers, giving the amount of active principle in the minimum dose. With the object of simplifying prescribing it is recommended that the symbol ʒ, which has been used to represent 60 grains and also a fluidrachm, and the symbol ℥ used to represent 480 grains, sometimes 437½ grains and also a fluidounce, should be discontinued, and that instead solids should be prescribed in grams and ounces (oz., 437½ grains) and liquids in minims (♏) and fluidounces (fl. oz.) and that quantities should be written in Arabic instead of in the much used Roman numerals. To avoid the possibility of confusion between gram and grain, the symbol G should be used as the contraction for the former. For all processes, chemical and pharmaceutic, the metric system of weights and measures is employed, but doses are expressed in both the metric and the imperial systems.

A considerable proportion of the drugs and preparations of the previous edition have been omitted on the ground that the British pharmacopeia is not a formulary but a book of standards. An arrangement has, however, been made that they will appear in the British Pharmaceutical Codex (which is an imperial dispensatory published by the Pharmaceutical Society). A number of drugs have been omitted on the ground of insufficient medical value. All the local preparations used in the tropical parts of the empire and the colonies have been excluded, because it is thought that these places should have their own local formularies. The whole group of hypodermic injections has been omitted, because it is considered that the physician should prescribe the dose of the active material as such, rather than an official hypodermic injection. Many formulas for powders and pills have been omitted, because it is thought that the combination should be left to the individual physician, though such widely used combinations as Dover's powder, Gregory's powder and black draft have been retained. The wines have been omitted in conformity with the international agreement for the unification of formulas for potent drugs, which requires that none shall be prepared in the form of a medicinal wine.

New introductions are ointments for the eye and industrial methylated spirit, which is permitted for the preparation of certain external remedies, and certain internal ones if the spirit is eliminated from the final product. The progress of organotherapy is reflected in the inclusion of such substances as insulin and pituitary solution. The dose of the latter is given in units only and not in volume because manufacturers are producing entirely different strengths, and physicians, unaware of the fact, have been prescribing by volume. Doses of digitalis are given both in units and in volume; the commission would have liked to give only the former but thought that the medical profession was not quite prepared for this. Of the vitamins only one, apart from cod liver oil, appears, for the reason that it is susceptible of standardization. Of vaccines only one, apart from that of vaccinia, appears; namely, the typhoid and paratyphoid (T. A. B.).

A White Australia: The Problem of the Half-Caste

Dr. Grenfell Price, who is going to America in September to investigate social conditions, particularly in the tropical regions, has returned to Adelaide from a preparatory inspection in North Australia, with much information about the aborigines. He considers that the problem of the future of the race is more important than has been realized. The marrying of half-castes to one another and to white persons was the policy for solving the problem which the physicians at Darwin considered the most hopeful. They told him that there had been no throwbacks as the result of these mixed marriages. The dark pigmentation of the skin disappears eventually. The raising of the wages of half-castes and pure aborigines involved conditions that might force pastoralists from the land. The future of the white Australia policy depended on the pioneer work of white women, who would prosper if temperamentally suited to the life and given proper facilities. It looked as though the policy might succeed in the tropical part of Australia.

A Provident Hospital Scheme for the Middle Classes

Many persons of the middle class are in the unfortunate position of not being subjects for the free medical treatment which the poor receive in serious illness nor able, on the other hand, to bear the great cost, as the rich can. Indeed, for them such an illness, especially if it includes a surgical operation, may be a financial disaster. As a remedy for this evil the British Provident Association has been formed. It aims at providing hospital and nursing-home beds at reasonable charges and covering substantially, if not wholly, the cost of maintenance during the illness, and the surgical fees. The association aims at securing 100,000 contributors of $50 each, so that by means of the money received it can obtain 1,000 beds in the existing voluntary hospitals or in new buildings, to be known as the association's "home hospitals." An important meeting of the association took place at the Mansion House under the presidency of the lord mayor of London. The chairman of the association, Lord Lloyd, said that it was estimated that there were in greater London 600,000 families (2½ million persons) belonging to the middle and professional classes, any of whom might at any time be in need of hospital accommodation for serious illness. In the voluntary hospitals of London, 1,500 beds were available for such a purpose, but many more were needed. While a payment of $50 will provide the benefits for a man and his wife and children up to the age of 21 years it has been decided to accept $25 from single persons who might have a difficulty in providing $50.

In supporting the scheme, Lord Moynihan said that surgery had now been made safe for the patient, but it remained to make the patient safe for surgery. For an operation, days or weeks of preparation might be necessary. Such a procedure as blood transfusion was now a commonplace, and this and other methods were possible only under institutional care. Only twice in the last twenty years had he performed an operation in a private house. Nursing homes gave fairly adequate facilities to the rich, but those who got the best from the surgical side of the profession were the poor, who partook of the benefits of the voluntary hospital system, one of the greatest glories of the country. But with regard to the middle class it had been one of the miseries of his professional life to feel that owing to the inadequate preparation possible to them they had either to be recipients of charity, which they generally detested, to strain their purses unduly to meet the necessary expense, or to ask the surgeon to forego part of his fee. He could say that two thirds of the work he had done in surgery was for no fee, and he was not distinguished from other surgeons in that respect. But that was not the right principle from the point of view of the patients themselves, for it made them reluctant to go to the surgeon again.

Lord Dawson of Penn said that the kernel of the difficulty was that side by side with decreased capacity to pay, owing largely to the financial situation, had grown up increased cost of treatment, resulting from the growth of medical knowledge. A few years ago such diagnosis as was possible was simple; now roentgen examination and chemical analyses might be necessary. The tendency today was to investigate disease in its early stages. He did not think that any scheme of insurance should be confined to serious illness; it should include methods of prevention. Illustrating the increase of cost, he said that the x-ray department of a hospital of 400 beds cost $750 in 1911, $3,750 in 1921, and $14,000 in 1931. There was only one way of meeting the needs of the nation, except for the fortunate few, by mass production. The last thing that anybody who knew the value of medicine would wish was that institutional treatment should replace the care of the patient in his own home by the family physician; but there must be insurance, which was becoming more a part of the fabric of the daily life of the people.

PARIS

(From Our Regular Correspondent)

July 13, 1932.

A Society to Combat Crime

A society has been formed in Paris, on the initiative of Dr. Toulouse, to study, in a group of psychiatrists, medicolegalists, jurisconsults and magistrates, the means of diminishing crime, and particularly that due to uncontrolled passion, which is increasing in France. The explanation is easily found in the extreme indulgence of the juries, who impose insignificant penalties or pronounce acquittals that are often scandalous. Not being in a position to influence the juries, Dr. Toulouse has founded the society of mental hygiene and created the Henri-Rousselle hospital, where free consultations are given in mental disorders. He believes that one can organize crime prevention by starting with the principle that every criminal is abnormal. If the psychiatrist were allowed to intervene, in time it would be possible to diagnose mental states which may become dangerous if left untreated. At the Henri-Rousselle hospital, the patients come of their own accord, although usually at the suggestion of their entourage, disquieted by their peculiar behavior or by their violent words and acts. The most dangerous subjects, however, are those who refuse to go to the hospital. The central problem therefore is to find some legal means to compel them to submit to an examination. It is a delicate matter, for the family physician must not violate the right of privileged communication and cannot report the subject to the authorities. All he can do is to give advice, which is seldom followed. French law does not permit intervention until misdemeanors have actually been committed. In that event, the entourage notifies the police commissioner, who, after securing a physician's certificate, has the subject transported to the special infirmary of the prefecture of police, where he is placed under observation for forty-eight hours in a prison cell, along with thieves and murderers. He is then either released or sent for a further surveillance to a psychopathic hospital, according to the judgment of the medical director of the infirmary, who is a competent psychiatrist but who has not the time nor the facilities for making a thorough examination at the infirmary. At its first meeting, the Société de prophylaxie criminelle proposed carrying out the plan of Professor Claude, which involves the creation of a special medicojudicial tribunal, composed of magistrates, psychiatrists and lawyers, before which persons presenting a mental state disquieting to themselves and to their entourage would be courteously invited to present themselves on the notification of any person having cause to complain of their behavior, and would be brought by force if they refused to come voluntarily. If the questioning and the psychiatric examination reveal only slight disorders that are not a menace to others, the subject would be placed under the observation of his family and would be urged to seek treatment in the center for mental prophylaxis If the disorders were of a more serious nature, he would transferred to a psychopathic hospital, from which, on dismissal, he would be subjected to a discreet surveillance by the police. These provisions are similar to those created for the organization, a few years ago, of the tribunals for incorrigible children. Many other questions dealing with this general subject have been based on the program of the society and have necessitated a division into several sections: influencing of legislation, organization of criminal prophylaxis, criminologic institutions and psychiatric annexes created within the prisons, modification of the criminal code, delinquent children, social factors influencing crime, sexologic criminology, and narcotic addicts and alcoholism. All these sections will present papers at the next meeting of the society.

July 18, 1932.

Meeting of the Prussian Council on Health

The committee on dermography and eugenics, of the Preussischer Landesgesundheitsrat, held a meeting, July 2, under the chairmanship of Ministerialdirektor Dr. Schopohl, to consider the importance and tasks of eugenics in the service of public welfare. In his opening address, the chairman called attention to the fact that the biologic heritage of the German people is menaced. With startling clearness eugenic researches show that the families with a sound heritage do not produce sufficient posterity to preserve the status quo, whereas the families with an unsound heritage are increasing unchecked, with the result that they are requiring more and more welfare aid at the expense and to the disadvantage of the families of sound heritage. Eugenic thinking, planning and acting are therefore needed. The desire to safeguard the future of our people may possibly awaken a consciousness of the need of mutual deliberation, whereas otherwise forces may remain at work that will lead to disharmony and the lack of mutual aid.

The meeting was attended by a large number of experts in the fields of hereditary research and psychiatry, medicine and jurisprudence, ethics and pedagogics, public and private welfare work, administration and politics. The speakers were Prof. Dr. H. Muckermann of the Kaiser-Wilhelm-Institut für Anthropologie, menschliche Erblehre und Eugenik; the psychiatrist Prof. Dr. J. Lange of Breslau, and Prof. Dr. Kohlrausch, an authority on criminal law, Berlin. The criteria presented by the speakers may be divided into three parts. The first part emphasized, in agreement with the resolution of the Prussian state council, dated Jan. 20, 1932, the need of a general plan of eugenic education, consisting primarily of instruction in the theory of heredity and in eugenics, and in the training of teachers, physicians and all persons who are engaged in welfare work. The research centers for theory of heredity and eugenics should be supported in spite of the present economic disturbances. Eugenic education should work toward the end that, in anticipation of a legal regulation as the ultimate goal, a voluntary exchange of health certificates before the engagement may become a family custom. The marriage consultation centers should furnish primarily eugenic advice.

The second part of the criteria deals with the necessity of adopting negative eugenic measures, in order to limit the unrestricted propagation of offspring with serious hereditary defects, which, in ever increasing numbers that are today scarcely endurable, fall a burden to the public welfare organizations; which fill the institutions for mental patients and weakminded persons, and which constitute a large portion of the social service material and the criminal class. In view of the fact that this goal cannot be attained by institutional care, the legal approval of a strict eugenic sterilization (not castration), under suitable controls, is demanded, although no general compulsory legislation is proposed. The destruction of seriously defective living human beings is not contemplated. The social aid given living persons with hereditary defects should not be discontinued, but the extent of the need of social aid service should be lessened by means of sterilization.

The third part of the criteria comprises, in supplementation of the eugenic education, the positive eugenic measures for the advancement of the family of sound heritage. Along with the providing of employment and the establishing of settlements or colonies, the granting of economic favors is to be considered: adjustments in the salaries of persons steadily employed, and reductions of taxes in keeping with the number of children and the family income.

After a lengthy discussion, the criteria were unanimously adopted with slight modifications. For the further elaboration of the question, especially as regards the legal side (sterilization), a commission was appointed that comprises, in addition to the chairman of the Prussian health council, Professors Muckermann, Lange, Kohlrausch and Ministerialrat Ostermann, and will be supplemented by physicians, jurists, theologians, teachers, and representatives of the public and the volunteer welfare services and the civil governments.

New Regulations Governing Medical Students

In the regulations concerning the examination in medicine there are some important changes, taking effect at once, that apply solely to the preclinical years, other changes being reserved for the clinical years. Whereas heretofore the preliminary test called the Physikum has followed the preclinical semesters, now a preliminary test must be taken after the first two semesters, which will include chemistry, physics, zoology and botany. After three more semesters, an examination is given in anatomy, general physiology and physiologic chemistry. Three semesters must intervene between the examination in the pure natural sciences and the anatomic-physiologic test. Until April 1, 1935, however, a transitional ruling provides that under certain circumstances two semesters may suffice.

For admission to the test in the natural sciences the candidate must present not only the graduation diploma of the preparatory school attended but also the so-called Latein-Nachweis, or evidence that he has completed a satsfactory course in Latin. The test in zoology and botany will cover mainly the elements of general biology with especial consideration of the theory of hereditary transmission.

It was finally decided not to hold special lectures in the natural sciences for medical students. It is, however, expected that the professors in the natural sciences will adapt their lectures to the needs of the medical students. If in the examination in the natural sciences the candidate does not secure at least the grade "satisfactory" in all the subjects, he has failed to pass. If he receives the grade "unsatisfactory" in only one subject, the candidate may be excused (in part or entirely) from a review of the subjects in which he had at least a passing grade. But if the candidate fails in two or more subjects, he must review all the subjects covered by the examination.

If the student obtains at least "good" in any subject of the examination, he is relieved of the necessity of reviewing that subject for a second test. The second examination will not ordinarily be given until after the lapse of a complete semester. If the student fails in as much as one subject of the second examination, he is absolutely excluded from taking a third test. Nor is the student permitted to begin his studies over again and thus secure a further admission to the test. The two preliminary tests must be taken within a period of twelve months; otherwise no credits obtained in any subjects will be recognized.

In view of the serious consequences that may arise from a mental disorder or mania in a person practicing the art of medicine, it has been decreed that, in the event of the existence of such a condition in an applicant, admission to the tests, the acceptance of an internship, and the securing of a license to practice will be withheld, if the fear appears justified that the candidate, on account of his disorder, may not be a reliable physician.

July 6, 1932.

Meeting of International Bureau of Medicomilitary Bibliography

The second session of the Office international de documentation médico-militaire was held at Liége, June 23-25. More than 200 representatives of twenty-six different nations, three of whom were from the United States, participated.

The opening meeting, held in the Palais du gouvernement provincial, was attended by a large proportion of the diplomatic corps accredited to Belgium, and by the chief officials of the city and the province. Governor Priard in the welcoming address expressed his gratification at seeing assembled an intellectually élite body whose ideals are devoted to the love of peace. Colonel Voncken, of the army medical corps of Belgium, the next speaker, outlined the great task to be performed in order that their mission with respect to peace and human welfare, the international training of military physicians, and the formation of bibliographic collections may be fulfilled. Professor Mahaim considered then, in the light of international law, the work of the military physician and more particularly the organization of international cooperation in this field. Colonel Van Baumberghen of the Spanish army, chairman of the permanent committee, declared the second session of the Office international de documentation medico-militaire to be formally opened.

Major Dendal discussed the menace of aerochemical warfare from the point of view of the protection of the civil population. While all war marks a return to barbarism, it is nevertheless an eventuality that must be recognized. Recent air maneuvers appear to indicate that aerochemical warfare will play a horrifying part in the deciding of a military campaign, but in reality numerous physical conditions will prevent its complete realization. The civil population must not underestimate the danger and must organize in time of peace for its protection and for the aid of victims of aerochemical attacks. At the close of Major Dendal's address, Governor and Madame Pirard received in their salons the notables present. The papers were presented, June 23-25, and a brief analysis of them will be given.

Major Van De Roemer, of the Netherlands army medical corps, explained the advantages of the use of water routes, not only as a means of evacuation but also as a means of transporting a complete sanitary unit. He described the installations that would be carried out in time of war, such as a surgical ship (1,000 and 500 tons), hospital ship, personnel ship, supply ship, and a ship for disinfection and disinfestation.

General Inspector Dopter, of the medical corps of the French army, called attention to the gravity of a diphtheria outbreak in the army. He pointed out the difficulties of vaccination in time of war. The use of the new hyperactive anatoxin has made it possible to obtain the same results with only two inoculations instead of three.

Captain Govaerts explained the modern conception of a lesson in gymnastics: the phase of getting one's stride, the phase of maximum effort, and the phase of a progressive return to a state of rest. He elucidated also the physiologic conceptions that have impressed on present-day gymnastics its peculiar character.

Colonel Thomann, pharmacist of the Swiss army medical corps, discussed the requirements of the individual first-aid kit carried by every soldier. He cited the conclusions of the commission on standardization on this point and demonstrated the different types of dressings in use in the various armies.

Lieutenant Colonel Vollenweider, of the Swiss army medical corps, showed what great care is taken in selecting the reserves in the Swiss army, and with what great diligence the physical training of the recruit is carried out. He explained also the procedure for invaliding for infirmities contracted in the army.

Commandant Taditch, of the army medical corps of Yugoslavia, discussed the organization and the functioning of the bacteriologic laboratories of the army in the field. The bacteriologic laboratory has considerable importance under ordinary conditions and might become exceedingly important in the event of bacteriologic warfare, the launching of which is a possibility.

Colonel Schickelé, of the French army medical corps, explained first the governing principles of the present organization: evacuation and hospitalization are not two distinct acts but are closely associated. He showed how improvements in the means of transportation had made it possible, within a few hours, to evacuate the wounded to a zone where they find adequate facilities for treatment. He discussed the mathematical data that will enable one to determine the extent of the facilities needed, on the basis of the number of men in action.

In this connection a resolution reading as follows was presented and turned over to the permanent committee of the Congrès internationaux de médecine et de pharmacie militaires:

The assembly of officers of the army medical corps of twenty-six nations, meeting at Liége on the occasion of the second session of the Office international de documentation de médecine militaire, hereby promulgates the following resolution:

> With a view to assuring the favorable hospitalization and prompt treatment of the sick and wounded in time of war, it is desirable that certain areas be reserved for the army medical service; that all organizations of military nature be excluded therefrom, and that these areas enjoy such immunity as is conferred by the convention of Geneva.

Lieutenant Colonel Vargas advocated a record card, which the wounded and sick will receive when their wounds are first dressed or medical treatment is given and which will accompany them during their evacuation toward the rear. This card differs from the model recommended by the commission on standardization but is nevertheless similar in style and content.

In addition to this series of communications, the permanent committee arranged with Colonel Schickelé, of the French army medical corps, for a public lecture to be delivered at the University of Liége. After placing at the foot of a monument erected to the memory of the university students who died in the war a magnificent wreath with the colors of military medicine, Colonel Schickelé entered the university auditorium, where the élite of the city was gathered with the Belgian and foreign members of the society. Colonel Voncken presented the speaker, who then gave an historical account of military medicine down through the centuries and pointed out not only the evolution of therapeutics but also the status of the military physician. He recalled the military physicians who stood out at the siege of Troy, and mentioned Ambroise Paré, Larrey and others. During this session, the mayor of the city of Liége, surrounded by his aldermen, turned over to the permanent committee certain rooms that he placed at the disposal of the Office de documentation. A reception given by the city of Liége brought together the delegates, the civil and military authorities, and the members of the Société liégeoise.

The government of the United States was represented by Commander William Seaman Bainbridge, member of the permanent committee of the Congrès internationaux de médecine et de pharmacie militaires, and Capt. W. H. Bell of the United States Marine Corps. Commander Bainbridge presented a communication in which he emphasized the efforts being put forth in the United States to secure the meeting at Washington, in 1935, of the eighth International Congress of Military Medicine. It appears, furthermore, that the heads of the medical departments of the army, the marine and public health are working to secure the collaboration of the United States government for the holding of the congress at Washington in 1935. The permanent committee of the Congrès internationaux de médecine et de pharmacie militaires held several meetings concerning the seventh congress, to be held at Madrid, May 2 1933.

The Belgian League of Dental Hygiene

The Ligue belge d'hygiène dentaire, created at the close of the International Exposition of Dental Hygiene, in August, 1930, at Brussels, has about completed its organization. Established on the initiative of the Association générale des dentistes de Belgique, it makes an appeal to all practitioners, stomatologists, dentists, and physicians interested in social hygiene—pediatricians and school health officers. The league has secured the patronage of the chief social organizations, which are continuing to give it the support that they gave to the congress. While the launching of a program requires time because of the need of collecting funds and equipment, it has been possible to organize some activities. Thanks to the aid of similar foreign organizations, the league was able to maintain for a year, in the quarters placed at its disposal in the Palais Mondial, a demonstration of dental hygienic propaganda. The original collections having been returned to the owners, the material is now rather reduced, but the league has been able to maintain a small nucleus and hopes to be able to develop it rapidly. In collaboration with the Red Cross of Belgium, it publishes at present various tracts in promotion of dental hygiene.

The Organization of Public Care of Children

Although there are in Rumania several laws, enacted in 1910, 1921, 1926, 1929 and 1930, relating to the protection of infants and children, they are inadequate to modern conditions. This is partly due to the undisciplined public and partly to lax enforcement of the laws. Another handicap to obtaining the full benefits from a well organized children's protection campaign is that the number of outlying organizations is small and they are unequally distributed in the different regions; there is no close cooperation between state and private protection of children; finally, the expenses are high: 163,000,000 lei yearly, about a million dollars.

These facts awakened the thought to lay the foundation of a new organization. At a meeting recently, it was resolved that the leaders of the present organization appeal to the government and suggest the passing of a law which shall establish the status of children really needing care, of whom there are about 15,000 in the land. The next step should be to organize a central bureau in the ministry of public health for all the ramifications of children's protection. In every one of the twelve principal towns and cities of Rumania there should be a children's protection central organization which would have to deal with social service, the establishing of children welfare homes, the appointment of traveling instructors to villages suitable for the purposes of children's colonies, and the establishment of children's hospitals and obstetric wards. Thus it would be possible to carry on children's care and protection work for about 133,000,000 lei yearly. The sum represents only one eighth of the sum spent in France for the same purpose, in spite of the fact that France's population is only two and a half times as great as that of Rumania. According to Dr. I. Nemoianu, an apostle of the cause of the care of children, the contemplated organization would shelter from 12,000 to 36,000 children annually, afford about 400,000 medical consultations and assist about 15,000 mothers, and sponsor between 300 and 400 lectures.

Calmette's Tuberculosis Vaccine

There is no law in Rumania which makes the use of B C G compulsory, yet at present antituberculosis vaccinations are being done in forty-eight towns and cities and in eight district dispensaries. The number of babies already vaccinated amounts to about 70,000.

The vaccinations, in general, are well tolerated. While the general mortality rate of nonvaccinated children has amounted to from 16.6 to 25 per cent, the rate for those vaccinated varies from 14.4 to 7.3 per cent. Among 17,535 children who were closely observed during 1929, there were 1,005 infants born and brought up in a tuberculous environment; the tuberculosis mortality rate of the latter could be established at 2.1 per cent. On the other hand, the rate among nonvaccinated ones amounted to between 15 and 30 per cent. In Bucharest, the general mortality rate of infants under one year (18 per cent) fell to 8 per cent among the vaccinated children. The Rumanian pediatric authorities unanimously believe that B C G should be given to all infants.

Exanthematic Typhus in Rumania

Typhus exanthematicus was quite unknown in Rumania in prewar times. It appeared first in 1917 and then sporadically and only in the vacinity of Bessarabia, then a part of Russia. Some sporadic cases occurred also in the provinces of Muntenia and Moldova, but it could be established with certainty that these cases affected in the stage of incubation persons coming from infected places.

The cause of the Bessarabian outbreak is easily found: the severe poverty prevailing all over Bessarabia; unhygienic, overcrowded dwellings; lack of personal and general cleanliness; bad nutrition; fresh infection brought continually by refugees coming from Russia; lack of means to combat the scourge, and last but not least the indolence of the public health staff, the members of which are not intelligent enough to perform their important duties. The incidence of the disease during the past autumn and winter was as follows: In October, 1931, the number of cases amounted to 6, in November to 11, in December to 34, in January, 1932, to 67, in February to 89, and in March to 61.

THE NETHERLANDS

(From Our Regular Correspondent)

July 6, 1932.

The Cinchona Monopoly

The cultivation of cinchona was taken up at the May, 1931, meeting of the permanent committee of the Office international d'hygiène publique. A reference was made to the alleged abuse of the Dutch "monopoly" of quinine. Dr. De Vogel, former chief inspector of the public health service in the Dutch East Indies, has published an article calling attention to the critical period during which the cultivation of cinchona in Java was menaced by speculations that caused unheard-of fluctuations in the price of cinchona bark. The government of the Dutch East Indies suggested a solution of the problem that led to the present agreement. The arrangement that has been made is fortunate; otherwise the ruin of the private cultivation of cinchona in Java would have brought about a scarcity of quinine.

The department of agriculture realized that the task associated with the government's cultivation of cinchona should include, above all, scientific research and the collection of information. One could not charge it also with the task of supplying the world's needs in quinine. It was clear that that was the task of private industry. The management considers the stability of prices the basis that will permit the solid establishment of an industry, capable of supplying all the demands that the growing need of quinine would create. This price stability could not be maintained except on the basis of an equilibrium between consumption and production.

The department of agriculture succeeded in convincing the planters' association of the importance of an understanding with the manufacturers of quinine by virtue of which the producers of cinchona bark would be certain of a market the volume of which could be fixed over a period of years. The manufacturers would be assured of regular supplies of cinchona bark, for which they would pay a price that would be in relation to the current price of quinine.

As a result of this action the speculators were prevented from getting possession of the product, but there was a danger that this "community of interests" would abuse its power by raising the price to a point at which quinine would be unavailable to the majority of patients with malaria. The government plantations supply about 10 per cent of the entire production of cinchona bark in the Dutch East Indies. The association was therefore interested in getting control of this supply. The government did not wish to subscribe to the arrangement other than on condition that each participant would promise to cooperate in furnishing quinine at a reasonable price and with the right reserved to withdraw within a year if it thought that the agreement was an obstacle to the supplying of malarial regions with quinine at a reasonable price. This stipulation was incorporated in the agreement in article 117.

The government has never tried to reserve for its own subjects, by special laws, this advantageous position. On the contrary, on several occasions, the government of the Dutch East Indies has furnished plants and selected seed to colonial powers that planned to introduce within their domains the cultivation of cinchona. When requested, it has given generously to other governments advice and information based on the results of research at its experimental plantation, and it has allowed other nations to profit from its experience acquired after great efforts embracing a period of more than seventy-five years.

Our success has sometimes been attributed to the favorable conditions for the cultivation of cinchona, associated with the soil and climate of the archipelago. Be it so; our laws throw open our territory completely to foreign enterprise, under the same conditions that they impose on our nationalists.

There is in our territory a large cinchona plantation belonging to the Italian government, called Chibitoe, which almost equals in extent our government plantation. It appears established that the government of the Dutch East Indies, in assuming the initiative to bring about close collaboration between the planters of cinchona and the manufacturers of quinine, saved private cultivation of cinchona from ruin and assured the world a supply of quinine. In 1851, the first attempts were made to transplant cinchona from South America to Java. It was not as a speculation but as an act of humanity that the government of Netherlands assumed responsibility for the carrying out of this enterprise.

The Health of Cement Workers

In the *Nederlandsch Tijdschrift voor Geneeskunde*, Van Bemmel has published an article in which he states that the extension of the cement and concrete industry has given rise in the Netherlands to fear for the health of the workmen. He comments on the results of an inquiry of the Netherlands bureau of labor inspection in 1930 and at the beginning of 1931.

Cement contains practically no free silica. After many years' work in the cement industry, the lungs have not usually undergone changes of a disquieting nature. Of 469 workmen employed in the cement factories or in the building industries, more than two thirds of whom had had more than five years of experience, there were found seventy-one slight disorders of the respiratory tracts (rhinitis, laryngitis, acute bronchitis); twenty-six cases of chronic bronchitis (or emphysema); eighteen cases of pneumonoconiosis, ten of which were discovered solely by a physical examination, five by a physical examination together with radiography, and three by radiography, and sixteen cases of tuberculosis without pneumonoconiosis. Other pathologic disorders found were acne, furunculosis, conjunctivitis, and the like. The pneumonoconiosis diagnosed by radiography had never reached the second stage.

The results of the inquiry made in the Netherlands confirmed those made elsewhere; namely, that the disorders caused by cement dust have a slight importance. If greater precautions are to be taken, they should be more in the improvement of the methods of work than in the individual measures of protection.

The Crusade Against Malaria

The commission on the antimalarial campaign in North Holland has published its report for 1930. The campaign actively followed for the destruction of mosquitoes in the dwellings has achieved success. The population is now recognizing the importance of this means of combating malaria. More than 13,000 families were visited and given a demonstration, during the year, the special film having been shown many times.

The number of cases reported in 1930 was 2,112, a morbidity of 42.3 per 10,000 inhabitants, as against 53, 35.4 and 34.5, respectively, for the three preceding years. More physicians have shown interest of late in the work of the commission. An indication may be derived from figures showing the notifications made monthly per physician: 9.7 in 1930 as against 8.4 in 1929. All these cases were verified by the presence of plasmodia in the blood.

JAPAN

(From Our Regular Correspondent)

June 31, 1932.

Health Insurance

With the hard times, health insurance, clinics, and a health union coming into being one after another, medical practitioners have been placed in a difficult situation throughout the country. The enforcement of the government health insurance has shown the people that physicians are able to treat patients for much smaller fees and the demand for smaller bills has been urgent. The demand not being met, some people applied to the government last year for a permit to establish a health union in Tokyo. This union is going to establish a hospital of its own with funds collected from members, who can have as many shares as they please at a cost of $5 each. This hospital is to be managed by a nonpractitioner. Shareholders or their families may be treated here.

There are about ten industrial guilds that have independent hospitals. This health union is almost the same in principle as the one mentioned before. For many reasons the state has hesitated but at last has permitted the formation of this union, against the strong opposition of the Japan Medical Association. A local medical association courageously fought against the industrial guild. It tried to require the guild doctors to obey the association's rules, which in some points are incompatible with service in such a hospital. A sensational lawsuit took place between the association and the guild doctors. The court decided that the medical association had no right to bind the doctor when he is working on a salary in a guild hospital, even if he is a member of the association. The plaintiff appealed to the court of appeal but lost. The Japan Medical Association has no longer any means to protect the majority of its members against this tendency of organized health unions. In a certain city, the practitioners all united to establish a private health insurance, which was not, of course, as financially beneficial as that of the government. In almost all the large cities the three kinds of hospitals or unions or insurance systems are going to fight it out with one another. Until the government health insurance enlarges its system so as to include all people in every station of society, no better solution will be found. A rapid change, at any rate, is expected to appear in medical circles in Japan.

Mountain Recreation for Delicate Schoolboys

The Imperial School Hygiene Society will open again the mountain health school for delicate children during the summer vacation this year. These children had been sent to the seaside sanatorium until year before last. Last year, for the first time, they were brought to the mountains, more than 3,000 meters above sea level, in the highland provinces near the Japanese Alps, that a comparison of the effect of the mountain school and the seaside school might be made. The mountains were found to be much more effective than the seaside. Three hundred delicate children from elementary schools in Tokyo and Yokohama, divided into two parties, were taken to the mountains for two weeks, and after they returned home they were carefully examined for six months. Among the boys and girls taken there, the boys of the sixth grade have increased, on the average, 2.6 cm. in height and 2.4 Kg. in weight, which is a remarkable increase when compared with that of ordinary boys of that age, 2.8 Kg. The girls of the same class and of the same age have shown an increase of 3.5 cm. in height and 3.2 Kg. in weight, while the ordinary girls' average increase is 3.8 Kg. The fifth grade boys (average age, 11) have increased 2.8 cm. in height and 3.9 Kg. in weight, while the ordinary boys of the same class increase 2.2 Kg. in weight. As for the girls taken there of the same age, their increase was 4.4 cm. in height and 3.7 Kg. in weight, which is an astonishing increase, if it is compared with that of other ordinary healthy girls, whose average increase is 2.7 Kg. in weight. The one year's experiment is not altogether sufficient to prove that mountain recreation is better than that at the seaside, but at least it has given some such indication.

Antidysentery Vaccination for Children

In the suburbs of Tokyo, the metropolitan police bureau sought to prevent children's dysentery from spreading by means of administration of a vaccine for internal use prepared at the Bacteriologic Research Institute. Types I and II and the "Ohara" bacillus are used to make tablets. The process is as follows: Cultures of the bacilli are mixed at the ratio of 200 mg. of bacilli to 1 cc. of a diluted formaldehyde-sodium chloride solution (1 part of solution of formaldehyde U. S. P. to 25 parts of physiologic solution of sodium chloride). It is left for forty-eight hours at 37 C. After the death of the bacilli is assured, 90 cc. of the mixture is added to 270 Gm. of lactose, 130 Gm. of amylogen, and some mint-oil. After being well mixed, it is strained and dried for eighteen hours at a constant temperature of 45 C. One gram of such a powder contains 45 mg. of bacilli of the three types. One tablet is made of 2 Gm. of this powder. Children between 3 and 5 years of age are given one tablet a day on an empty stomach.

In 1931, 119,904 children were so treated, and among them 535 had dysentery and 222 died. In the same locality 430,499 children of the same age had not been given this preventive, and among them 4,553 were attacked by this disease and 2,235 died of it. Encouraged by this result, the bureau gave this preventive to more than 500,000 children in May and June this year.

Memorial to the Late Baron Kitasato

Friends and disciples met the other day to consider the establishing of a memorial to the late Dr. Kitasato, the most generally recognized benefactor in medical circles in Japan. They came to a unanimous decision to establish a memorial library of medicine in Tokyo, and Count Kiyoura, one of the elder statesmen, was elected chairman of the committee to carry out the plan. As this kind of medical library will be the first one in this country, it is much desired that it be established as soon as possible.

School of Hygiene and Public Health

Owing to the world-wide depression, the offer from the Rockefeller Foundation to the school of hygiene and public health to be built in the near future has been postponed until better economic conditions return. But the candidates for membership who are in America it is believed will continue their studies. The establishment of the school, it is now hoped, will go ahead with funds from the state independent of the receipt of funds from the Rockefeller Foundation.

Marriages

Charles Edwards Parsons, Twillingate, Newfoundland, to Dr. Malvina Elizabeth Moore of Oakland, Calif., June 30.

Harold Benjamin Smith, North Wilkesboro, N. C., to Miss Mary Richardson McLeod of Cheraw, S. C., June 11.

Joshua Jack Grizzard, Jr., to Miss Ruth Corinne Cleek of Hot Springs, Va., in Richmond, June 22.

Frederick Lionel Finch, Jr., to Miss Melba Mayhew Gravely, both of Richmond, Va., June 23.

James Earle Wheeler, Belleville, Ill., to Miss Catherine Louise Davis of Beloit, Wis., June 18.

Delbert T. Sayter, Aldie, Va., to Miss Martha Garnett Gresham of Newport News, May 15.

Edward A. Yurick, Cleveland, to Miss Mary Josephine Hodock of Byesville, Ohio, June 27.

Thomas Meredith Winn, Covington, Va., to Miss Violet Gary of Kenbridge, June 30.

Roshier W. Miller to Mrs. Sallie Knight Hill, both of Richmond, Va., July 6.

Justin E. McCarthy to Miss Mary McConn, both of Cincinnati, April 5.

Deaths

Francis William Alter ⊕ Toledo, Ohio; Bellevue Hospital Medical College, New York, 1896; member of the American Academy of Ophthalmology and Oto-Laryngology; fellow of the American College of Surgeons; director and past president of the Toledo Academy of Medicine; past president of the Lucas County Medical Society; medical superintendent of the Alter Eye, Ear, Nose and Throat Hospital; for many years on the staffs of the Mercy Hospital and St. Vincent's Hospital; aged 65, died, July 19, in the Toledo Hospital, of carcinoma of the colon.

Paul J. Gelpi ⊕ New Orleans; Medical Department of the Tulane University of Louisiana, New Orleans, 1896; past president of the Louisiana State Medical Society and the Orleans Parish Medical Society; formerly professor of genito-urinary diseases and cystoscopy, Graduate School of Medicine, Tulane University of Louisiana; on the visiting staff of the Charity Hospital and the Hotel Dieu Hospital; aged 57; died, July 19, in Bay St. Louis, Miss., of chronic myocarditis and arteriosclerosis.

Karl W. Doege ⊕ Marshfield, Wis.; Medical Department of Western Reserve University, Cleveland, 1890; member of the House of Delegates of the American Medical Association in 1910, past president of the State Medical Society of Wisconsin, fellow of the American College of Surgeons; president of the Marshfield Clinic; surgeon in chief at St. Joseph's Hospital; aged 65; died, June 28, of heart disease.

Neal Luther Hoskins ⊕ Detroit; Detroit College of Medicine, 1905, associate professor of medicine at his alma mater; fellow of the American College of Physicians; consulting physician to St. Mary's Hospital; on the adjunct staff in the department of medicine, Harper Hospital; visiting physician to the Detroit Tuberculosis Sanitarium; aged 55; died, July 21, of carcinoma of the sigmoid.

Joseph Angevine Turner, Columbus, Ohio; Starling-Ohio Medical College, Columbus, 1911; member of the Ohio State Medical Association; served during the World War; on the staffs of the Columbus Radium Hospital, White Cross Hospital, St. Ann's Hospital and Grant Hospital; aged 44; died, June 25, of cirrhosis of the liver, hypostatic pneumonia and heart disease.

Frank A. Jacobson, Newburgh, N. Y.; New York Homeopathic Medical College and Hospital, 1888; member of the Medical Society of the State of New York; formerly member of the board of health and board of education; on the staff of St. Luke's Hospital; aged 68; died, July 9, in the Presbyterian Hospital, New York, of carcinoma of the esophagus.

Charles Sumner Holden, Attleboro, Mass.; Harvard University Medical School, Boston, 1883; member of the Massachusetts Medical Society; for ten years member of the state legislature; formerly member of the board of health of Attleboro; aged 76; died, July 3, in the Sturdy Memorial Hospital, of hypertrophy of the prostate and cystitis.

Benjamin James Baldwin, Montgomery, Ala.; Bellevue Hospital Medical College, New York, 1877; member and past president of the Medical Association of the State of Alabama; for twenty-seven years president of the board of education of Montgomery; aged 75; died, July 10, in St. Margaret's Hospital, of acute intestinal obstruction.

Philip Herrin, Villa Grove, Ill.; Barnes Medical College, St. Louis, 1903; member of the Illinois State Medical Society; secretary and past president of the Douglas County Medical Society; veteran of the Spanish-American and World wars; formerly bank president and mayor; aged 54; died, July 18, of cerebral hemorrhage.

Louis Leon Frisque, Chicago; Northwestern University School of Medicine, Chicago, 1911; member of the Illinois State Medical Society; fellow of the American College of Surgeons; on the staff of the Ravenswood Hospital; aged 49; died, July 27, in the Sacred Heart Sanitarium, Milwaukee, of encephalomalacia.

James Bartley Given, Jr. ⊕ Brooklyn; Columbia University College of Physicians and Surgeons, New York, 1921; fellow of the American College of Surgeons; on the staffs of the Carson C. Peck Memorial Hospital, Brooklyn Hospital and St. John's Hospital; aged 36; died, July 25, of heart disease.

Sylvan De Nux, Marksville, La.; University of the South Medical Department, Sewanee, Tenn., 1900; member of the Louisiana State Medical Society; member of the state board of health; coroner of Avoyelles Parish; aged 52; died, July 5, in the Baptist Hospital, Alexandria, of septicemia.

Roland Curtin Evans, Leighton, Ala.; University of the South Medical Department, Sewanee, Tenn., 1905; member of the Medical Association of the State of Alabama; veteran of the Spanish-American and World wars; aged 56; died, June 27, in the Colbert County Hospital, Sheffield.

Joseph E. Spatz, Medford, Ore.; Hahnemann Medical College and Hospital, Chicago, 1885; formerly member of the state board of health of Nebraska; for nine years member of the board of education in Fairfield, Neb.; aged 72; died, May 7, of organic heart disease.

George Albertson Parker, Jr., Newton, Pa.; University of Maryland School of Medicine, Baltimore, 1910; member of the Medical Society of the State of Pennsylvania; served during the World War; aged 49; died, July 15, in a hospital at Philadelphia.

Charles A. Hamilton, Waterbury, Conn.; University of Vermont College of Medicine, Burlington, 1886; member of the Connecticut State Medical Society; aged 83; died, July 12, of injuries received when his automobile went over an embankment.

Thomas Collins Stevenson Marshall ⊕ Washington, D. C.; Howard University School of Medicine, Washington, 1883; vice dean emeritus and emeritus professor of pathology at his alma mater; aged 76; died, June 29, of cerebral hemorrhage.

William Franklin Harpel, Chicago; Hahnemann Medical College and Hospital, Chicago, 1905; formerly professor of physiology and biology at his alma mater; aged 75; died, June 10, of chronic myocarditis, prostatitis, cystitis and arteriosclerosis.

Seaborn Jennings Fuller, Magazine, Ark.; University of Louisville (Ky.) School of Medicine, 1891; member of the Arkansas Medical Society; fellow of the American College of Surgeons; aged 63; died, April 7, in Little Rock, of heart disease.

Samuel G. Burkholder, Reading, Pa.; Harvey Medical College, Chicago, 1898; Northwestern University Medical School, Chicago, 1899; member of the Medical Society of the State of Pennsylvania; aged 61; died, May 10, of heart disease.

Joseph Daniel Tuten, Lake Charles, La.; Vanderbilt University School of Medicine, Nashville, Tenn., 1900; member of the Louisiana State Medical Society; on the staff of St. Patrick's Sanitarium; aged 54; died, July 13, of heart disease.

Samuel Streghorn Beakley, San Antonio, Texas; University of Nashville (Tenn.) Medical Department, 1900; member of the State Medical Association of Texas; aged 63; died, July 4, in the Nix Hospital, of acute dilatation of the heart.

Edmund I. Hinkle, Burlington, Ind.; University of Louisville (Ky.) School of Medicine, 1894; member of the Indiana State Medical Association; aged 63; was found dead in his automobile, July 3, of heart disease.

John Conrad Anderson, Indianapolis; Central College of Physicians and Surgeons, Indianapolis, 1905; member of the Indiana State Medical Association; aged 73; died, July 3, of uremia and chronic nephritis.

Christopher Gadsden Hay, Savannah, Ga.; University of Georgia Medical Department, Augusta, 1885; Confederate veteran; aged 84; died, July 2, of chronic interstitial nephritis and myocardial insufficiency.

James Bell Goddard, Eau Claire, Wis.; Rush Medical College, Chicago, 1888; member of the State Medical Society of Wisconsin; aged 75; died, June 25, in Freeport, Ill., of carcinoma of the throat.

John Sedgwick Dean, Glendale, Calif.; University of Michigan Medical School, Ann Arbor, 1889; aged 68; died, May 6, of sclerosis of the coronary artery, angina pectoris and diabetes mellitus.

Edwin Frank Wood, Rochester, N. Y.; University of Buffalo School of Medicine, 1917; member of the Medical Society of the State of New York; aged 47; died, July 10, of heart disease.

Cornelius C. Vanderbeck, St. Louis; Jefferson Medical College of Philadelphia, 1872; member of the Missouri State Medical Association; aged 80; died, June 15, of cerebral hemorrhage.

William Edward Wright, Fairfield, Ala.; Birmingham Medical College, 1907; member of the Medical Association of the State of Alabama; aged 48; died, July 13, of pulmonary tuberculosis.

Audley Emmet Nelson, Sidney, Iowa; Jefferson Medical College of Philadelphia, 1897; aged 64; was instantly killed, June 13, when the automobile in which he was driving overturned.

John Constantine Bialas ⊕ Utica, N. Y.; Boston University School of Medicine, 1916; on the staff of the Memorial Hospital; aged 39; died, June 28, of periprostatic abscess and embolism.

Robert Perry Jones ⊕ Baton Rouge, La.; Fort Worth School of Medicine, Medical Department of Fort Worth University, 1898; aged 59; died, May 23, of myocarditis and nephritis.

William C. Mitchell, Philadelphia; Jefferson Medical College of Philadelphia, 1893; aged 79; died, June 24, in the Jefferson Hospital, of cerebral hemorrhage and diabetes mellitus.

Robert Patrick, Woodville, Miss.; Medical Department of the University of Louisiana, New Orleans, 1873; aged 86; died, May 28, of hypertrophy of the prostate and nephritic toxemia.

John S. B. Woolford, Roswell, N. M.; University of Maryland School of Medicine, Baltimore, 1896; fellow of the American College of Surgeons; aged 60; died, July 4, of uremia.

Jean Samuel Holloway, Phoenix, Ariz.; Indiana University School of Medicine, Indianapolis, 1911; aged 44; died, June 29, in a hospital at Los Angeles, of hemorrhage of the lungs.

Benjamin F. Armbruster ⊕ Milwaukee; Hospital College of Medicine, Louisville, Ky., 1902; on the staff of St. Luke's Hospital; aged 59; died, July 4, of cerebral hemorrhage.

Charles Clinton Cracraft ⊕ Claysville, Pa.; Jefferson Medical College of Philadelphia, 1883; secretary of the Washington County Medical Society; aged 76; died, May 13.

Henry Whipple Allport, Chicago; Cornell University Medical College, New York, 1899; served during the World War; aged 67; died, July 27, of angina pectoris.

Robert Lee McLellan, Eagle Lake, Texas; Medical Department of the University of Alabama, Mobile, 1897; aged 61; died, July 8, in Smithville, of myocarditis.

Eber Devello McKinley ⊕ Alamogordo, N. M.; Central College of Physicians and Surgeons, Indianapolis, 1904; aged 55; died, May 17, of coronary embolism.

Ira Calvin Hoffman, Aliquippa, Pa.; College of Physicians and Surgeons, Baltimore, 1915; also a druggist; aged 56; died, July 18, of carcinoma of the stomach.

Robert James Haworth, Vancouver, B. C., Canada; University of Manitoba Faculty of Medicine, Winnipeg, Manit., 1892; aged 78; died in March.

Hugh J. Needham, New Albany, Ind.; Pulte Medical College, Homeopathic, Cincinnati, 1881; aged 89; died, June 23, of chronic nephritis.

William Raymer, Beaver Falls, Pa.; Homeopathic Hospital College, Cleveland, 1878; aged 76; died, June 28.

John G. Slappy, Jeffersonville, Ga.; Atlanta Medical College, 1875; aged 78; died, June 27.

Bureau of Investigation

CROXON CREAM

An Alleged Depilatory from Koremlu Antecedents

Readers of this department of The Journal will remember what has been published both recently and some months ago regarding a pernicious depilatory known as "Koremlu," which had for its active ingredient thallium acetate As was pointed out in the last article on Koremlu the number of cases of serious poisoning, with resultant damage suits brought against the exploiters, resulted in Koremlu, Inc, filing a voluntary *petition in bankruptcy*, *listing liabilities over two million dollars* and assets under three dollars

A few months ago the Bureau of Investigation began receiving inquiries regarding a newcomer to the depilatory field, sold under the trade-marked name "Croxon Cream" by Croxon, Inc The address of Croxon, Inc, was Suite 1368, 20 West 43d Street New York City Investigation proved this to be the same office as that occupied by Koremlu, which used the address 11 West 42d Street, the building in which the two concerns were housed running through from 42d Street to 43d Street

It is reported that Croxon was incorporated in January, 1932, with an authorized capital of 2,000 shares of common stock at no par value Its president was given as A W Lublin This, presumably is the same A W Lublin who signed letters for the Koremlu concern as its vice-president

Croxon Cream is advertised in much the same way that Koremlu Cream was advertised In fact the style and illustration used in magazine "copy" of Koremlu and Croxon are almost identical Croxon Cream is sold under the definite claim that it will *permanently* remove hair If one is to believe the booklet on Croxon Cream, "thousands of experiments" were made in the alleged research that led to the discovery of this marvelous preparation To quote from the advertising booklet that goes with the trade package

> "The principle underlying the Croxon treatment is entirely new A combination of gentle chemical reactions *dissolves both hair and its root* [Italics ours—Ed] without injury to the health and vitality of the skin for they are similar to the reaction constantly taking place in all living cells "
>
> "Croxon is the perfect solution to the problem of superfluous hair It proves a simple, positive and permanent method guaranteed to *harmlessly destroy wherever used both hair and root* [Italics ours—Ed] so that no unwanted hair can ever grow there again
>
> " it [Croxon Cream] does not affect anything but the hair and hair root "

At this point our readers may be reminded of the unfortunate fact that drug products sold for cosmetic purposes, and not for the treatment or alleviation of disease, are free from the restrictions imposed by the national Food and Drugs Act That is why cosmetic manufacturers can falsify with impunity in statements accompanying the trade package Referring again to the alleged scientific research on which the creation of Croxon Cream is said to be based, the public is told in a page devoted to the statement that

> Professional ethics forbid the publication of the names of the doctors and scientists who made Croxon possible for your use

Last May, Croxon, Inc wrote to a woman who had inquired about the possible harmfulness of the preparation

> As Croxon Cream is a product of one of the largest hospitals in New York City and the research work has been done by dermatologists and toxicologists connected with the hospital, we do not think any further evidence is necessary '

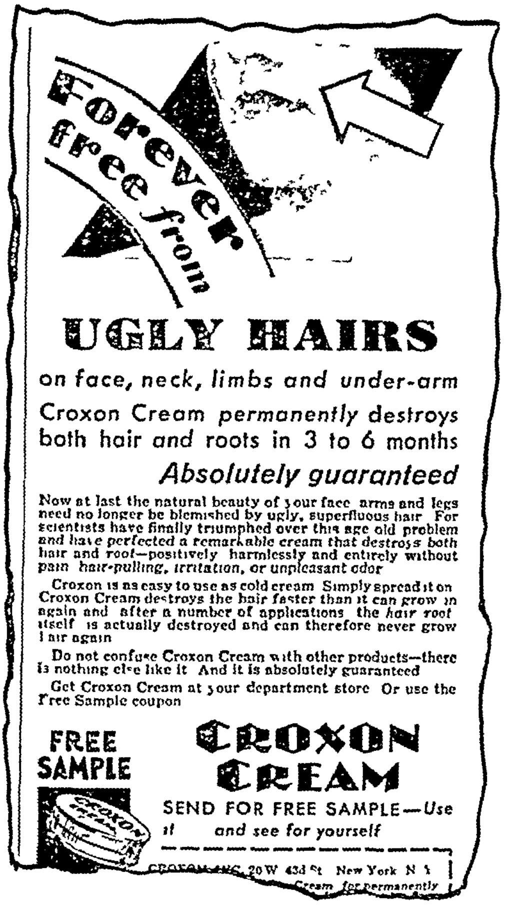
In the same letter Croxon, Inc, answering its correspondent s question as to where the company had obtained her name wrote

> 'As to how we got your name will say that we rent lists of names from manufacturers of cosmetics and other preparations We probably found your name on one of these lists as a good many houses sell or rent their lists of names

As long ago as last May, the National Better Business Bureau wrote to the Bureau of Investigation asking for any information that might be available on Croxon Cream At the same time they stated that they had seen a certificate from Helene Lemberger, Ph D, Department of Biochemistry, New York Post-Graduate Medical School and Hospital, that read as follows

> I hereby certify that the research investigation upon which the formula of Croxon Cream has been based, demonstrates that
>
> (*a*) It contains no compounds that are toxic as embodied in this preparation and when applied as directed
>
> '(*b*) It removes superfluous hair when applied as directed
>
> "(*c*) It prevents the regrowth of the hair when applied as directed over a period of one year
>
> '*It is my understanding that neither this letter, my name, nor the name of this institution will be used in advertising*'

Dr Lemberger's testimonial for Croxon Cream was referred to incidentally in the last article that was published in this department of The Journal on Koremlu Shortly after publication the Bureau of Investigation received a letter from John A Killian, Ph D, Director of the Department of Biochemistry of the Post-Graduate Medical School and Hospital



Forever free from

UGLY HAIRS

on face, neck, limbs and under-arm

Croxon Cream *permanently* destroys both hair *and* roots in 3 to 6 months

Absolutely guaranteed

Now at last the natural beauty of your face arms and legs need no longer be blemished by ugly, superfluous hair For scientists have finally triumphed over this age old problem and have *perfected* a remarkable cream that destroys both hair and root—positively harmlessly and entirely without pain *hair-pulling, irritation, or unpleasant odor*

Croxon is as easy to use as cold cream Simply spread it on Croxon Cream destroys the hair faster than it can *grow* in again and after a number of applications the *hair root* itself is actually destroyed and can therefore never grow hair again

Do not confuse Croxon Cream with other products—there is nothing else like it And it is absolutely guaranteed

CROXON INC 20 W 43d St New York N Y

Cream for permanently

Reproduction of advertisement of Croxon Cream appearing in recent issues of some national magazines

In his letter Dr Killian stated (1) that Dr Lemberger s work on Croxon Cream was not a part of the business of the laboratory of the Department of Biochemistry, (2) that the use of official stationery for the expression of her opinions was a violation of the rules of the laboratory and (3) that as Dr Lemberger s letter lacked his signature as Director of the Department, it was not an official report

All this made interesting reading, because in the meantime evidence had been received by the Bureau of Investigation that indicated that Dr Killian himself had done work on Croxon Cream It appears that Charles C Johnson, treasurer of Croxon Inc, in talking to someone who had inquired of him regarding the possible toxicity of Croxon Cream, had declared that Croxon Cream could not be poisonous because it had been tested and certified by the Post Graduate Hospital and that Dr Killian had done the work

In acknowledging Dr Killian's letter relative to the unofficial character of Dr Lemberger s testimonial, he was asked to furnish, either direct or through Dr. Lemberger, scientific evidence for the claims Dr. Lemberger had made to the effect that Croxon Cream (1) "removes superfluous hair when applied as directed" and (2) "prevents the regrowth when applied as directed over a period of one year."

Dr. Killian was also asked whether the New York Post-Graduate Medical School and Hospital had, as such, done any work on Croxon Cream or if Dr. Killian himself had done any work on the preparation and, if he had, whether that work was done in his capacity as Director of the Department of Biochemistry of the New York Post-Graduate Medical School and Hospital, or merely as a private chemist. Dr. Killian replied to the questions, thus:

> "Dr. Helene Lemberger is not in this laboratory at the present time and will not return to it. I shall answer the questions concerning the evidence upon which she based her statements in the letter referred to above. Her statement that the product called Croxon Cream removed superfluous hair was based upon observations of guinea-pigs receiving daily applications of the product, and also upon human subjects receiving applications of the cream on arms, legs and in the axillae. Secondly, as far as I can determine from her experimental data, she had, at the time the letter was signed (April 12), no evidence that it will prevent the regrowth of hair when applied as directed over a period of one year.
>
> "In answer to the question asked in your letter to me re Croxon Cream, I wish to say that beginning May 28th, 1932, an investigation of Croxon Cream has been carried on in the Department of Biochemistry under my supervision. The object of this investigation has been to determine (a) whether Croxon Cream will remove hair from experimental animals, and (b) to determine whether Croxon Cream, when applied as a depilatory cream, produces any toxic effect. This investigation has been, since May 28th, a part of the business of the laboratory. No report has been issued to date on our results. When the experiments have been completed to our satisfaction, the results will be published to the medical profession first. In this investigation we are following a plan similar to that adopted for the investigation of Koremlu. Other phases of the investigation of Croxon Cream are being worked out in other laboratories."

From this it will be seen that neither Dr. Lemberger's work nor Dr. Killian's work furnishes evidence for the claim that Croxon Cream "dissolves both hair and its root" so that "no unwanted hair can ever grow there again."

It may not be inappropriate to remind our readers at this point that it was Dr. Killian who furnished the elaborate report for the Scott Paper Company relative to the alleged virtues of "Scot Tissue" as compared with the (also alleged) vices of most of the other toilet papers on the American market.

Because of the close connection, at least in its genesis, between Croxon Cream and Koremlu Cream, it seemed desirable to find out as early as possible whether Croxon Cream might be another thallium acetate preparation. For that reason the A. M. A. Chemical Laboratory was asked to analyze the product. Their report follows:

LABORATORY REPORT

"An original jar of Croxon Cream (Croxon, Inc., 20 West 43d Street, New York), purchased on the open market (Price $10) was submitted to chemical examination.

"The jar contained 94.6 Gm. (approximately 3 ounces) of a cream-colored ointment, almost odorless. Qualitative tests indicated the presence of sodium, zinc and boron compounds, oxygen in the form of peroxide, and petrolatum. Heavy metals (such as mercury, lead, arsenic, antimony, etc.), alkaline-earth metals (such as barium, strontium, calcium and magnesium), chlorides, phenol or salicylic acid, sulphur compounds (including sulphides) were not found. Petrographic examination of the solid material in the ointment revealed a substance similar in the optical-crystalline properties to sodium perborate, zinc peroxide and zinc oxide. Quantitative determinations yielded the following:

Petroleum-benzin extract	68.0 per cent
Residue insoluble in petroleum benzin	31.0 per cent
Ash (750°)	20.4 per cent
Sodium (Na^+)	2.5 per cent
Boron (B)	1.1 per cent
Zinc (Zn^{++})	10.6 per cent
Total titratable oxygen (peroxide oxygen)	2.8 per cent
Titratable oxygen in water insoluble portion	1.3 per cent
These results may be calculated to:	
Sodium perborate ($NaBO_3 \cdot 4H_2O$)	15.0 per cent
Zinc peroxide (ZnO_2)	7.6 per cent
Zinc oxide (ZnO)	6.8 per cent

"From the foregoing, it may be concluded that the product contains essentially 15 per cent of sodium perborate, 7.6 per cent of zinc peroxide, and 6.8 per cent zinc oxide. Zinc peroxide is seldom pure but generally a mixture containing from 45 to 55 per cent zinc oxide. For practical purposes it appears, therefore, that the product consists essentially of approximately 15 per cent sodium perborate and 15 per cent commercial zinc peroxide incorporated in a petrolatum base."

From this it appears that Croxon Cream is essentially a mixture of sodium perborate, zinc oxide and zinc peroxide in a petrolatum base—three ounces (3 oz.) for ten dollars ($10). The amount of petrolatum, sodium perborate, zinc peroxide and zinc oxide found in a ten-dollar jar of Croxon Cream could be purchased at wholesale for less than 10 cents.

While Croxon Cream has none of the viciously dangerous elements found in Koremlu Cream, it is, as every dermatologist will recognize, quite worthless as a depilatory for either the temporary or the permanent removal of hair. What Croxon Cream will do, if rubbed into the skin from one to three times a day over a period of months as recommended, is to bleach the hair. The purchaser is told that it will be necessary to use Croxon Cream for from three to twelve months. As Croxon, Inc., get $10 for a three-ounce jar of Croxon Cream, the ingredients of which probably cost not more than a dime, will it make very much difference to the concern how many disappointed customers it may have if it can only get enough customers started on the three to twelve months' use?

Reverting again to Koremlu: It will be remembered that in the exploitation of Koremlu Cream, the Koremlu concern put out, as an accessory, what they called "Koremlu·Wax." Purchasers of Koremlu Cream who were in a hurry to have the hair removed were urged to purchase the "wax" in addition to the "cream." In the case of Croxon Cream, those who, after purchasing a ten dollar jar and finding after weeks of use that the superfluous hair is as thick as ever, are told to purchase "Croxon Depilatory Powder."

Croxon Depilatory Powder is just another one of the sulphide mixtures. It is described as a dainty, harmless, pleasant and non-irritating product." In spite of a valiant but wholly unsuccessful attempt to cover up its odor with perfume, it smells, in fact, like rotten eggs and decaying cabbage (hydrogen sulphide). As to its harmlessness, it may, like any of the alkaline sulphides, if not used with the greatest of circumspection, not merely remove hair, temporarily, but also remove the skin. It is worth noting, too, that the Croxon booklet states that where the hair has been "burned off" with depilatories, the time over which Croxon Cream must be used will be greatly increased.

On the closing page of the Croxon Cream booklet, Croxon, Inc., publish an alleged guarantee to the effect that those who purchase and use Croxon Cream as directed "will be permanently relieved of all trace of superfluous hair." In this connection, it is worth bringing back to mind the "guarantee" that the Koremlu people published, to the effect that after using from $20 to $240 worth of Koremlu, if you were dissatisfied with the results, the Koremlu people would return your money. As Koremlu, Inc., is bankrupt, with less than $3 in the till and over $2,500,000 owing, how much is the guarantee worth?

Correspondence

INJURY TO FACIAL NERVE IN MASTOID OPERATION

To the Editor:—In mastoid operations the danger of injury to the facial nerve is apparent, and the anesthetist is requested to watch for any twitching of the muscles about the eyes or the face to safeguard this nerve from being injured unawares. With the usual sterile coverings it is very difficult to see the face with much certainty. I have for many years used the sense of touch for this purpose, which is much more certain, and easier of application, by placing the finger at the angle of the mouth on the buccinator muscle.

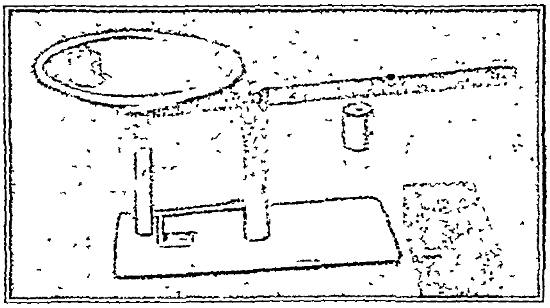
If the facial nerve is touched, contraction of these muscles is detected at once by the palpating finger, however slight the contraction may be.

James G. Poe, M.D., Dallas, Texas.
Baylor University Hospital.

SCALES FOR DIABETIC PATIENTS

To the Editor:—Charity patients in diabetic clinics seldom can afford to buy scales, yet weighed diets are conducive and at times indispensable to the treatment of diabetes. To supply this want, some of my patients in the diabetic section of the Falk Clinic, conducted by the University of Pittsburgh, constructed balance scales with metal picked out of the scrap piles, at the initial cost of 2½ cents. They are assembled by unemployed men and are calibrated to weigh within half a gram, by an expert, again unemployed.

A number of these scales were finished, as shown in the accompanying illustration, and distributed to deserving patients.



Balance for diabetic patients.

Beneficial results immediately became apparent, and in addition to the increased interest on the part of the entire group in their dietetic problems, patients were provided with an accurate means of weighing their total caloric intake regardless of their financial condition.

The social service department of the clinic has been requested to follow up those patients who have received such mechanical aids so that each set of scales will do maximum duty.

With the thought that others might wish to use this plan in solving similar problems, the matter is presented here

J. West Mitchell, M.D., Sewickley, Pa.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed Every letter must contain the writer's name and address, but these will be omitted, on request.

ENDOCARDITIS AFTER SCARLET FEVER

To the Editor:—In January of this year my son, aged 9 years, contracted scarlet fever This left an endocarditis as a sequela In spite of bed rest, a wholesome appetite and diet, and outward appearances of health, he persists in having a half degree of fever almost daily, and the systolic mitral lesion is gradually becoming more accentuated For two weeks following tonsillectomy his condition seemed aggravated, his temperature being elevated from 1 to 1.5 degrees, and his pulse was correspondingly accelerated. I have had him on salicylates, streptococcus vaccines, iron tonics and sun baths, but this low grade process continues in spite of all effort and his apparent well being I will be pleased to learn of any more therapy you might recommend in this case Please omit name.

M.D , Iowa.

Answer.—It is possible that the endocarditis described is the result of a complicating rheumatic fever. This is an important distinction to make because joint pains and rheumatic nodules may aid in determining the state of activity of the process. With either causation the child's weight curve at this stage of the disease would be a helpful index of activity or the nonexistence of the latter. As the query suggests, the temperature curve is important also; but this should be recorded in the absence of salicylates, to be significant. Even then it is difficult to interpret a fever of half a degree this long after the onset of the child's illness. Opinions may be had on both sides of this question, but many clinicians would favor disregarding this amount of fever in the absence of salicylate medication in a hild of this age. An electrocardiograph tracing for evidences of disturbed conduction not detectable clinically in any other way would be of considerable significance, if positive.

If the boy is gaining a little in weight and shows no evidence of active rheumatic fever or of active endocarditis, other than the half degree of fever, and the electrocardiographic tracing is normal, discontinuation of medication and a gradual resumption of activity for the patient may be recommended. As Dr. Herrick and others have pointed out, physicians have sometimes erred in the past in making more of an invalid out of such a patient than the necessities of the case demand.

The existence of evidence of activity on any of the scores mentioned would justify the continuation of bed rest. Rest and good food and other general hygienic measures are the most valuable parts of therapy of the active stage. The value of other forms of treatment remains highly problematic. The salicylates are favored if joint involvement is present, and some believe in their use for the endocarditis itself.

FILARIASIS OR ABNORMAL LYMPH CHANNELS

To the Editor—A woman, aged 26, a nullipara, has a large edema of the right foot ascending and diminishing in size till just below the knee No discoloration, redness or pain is present, nor is there impaired arterial circulation. The Wassermann test is negative. Blood counts are normal. There is no x-ray evidence of a pathologic condition of the bone and no sign of tuberculosis The condition suggests a stasis in the lymphatics, although no enlarged lymph glands can be felt anywhere The swelling has existed since her childhood, about twenty years, but has increased during the last half year. Several years ago in France she received punctate cauterizations at the metatarsophalangeal joints. She states that these resulted in some benefit at the time. Up to her sixth year she lived in French Guiana, and afterward in France. I was advised to look for filariae. Blood smears taken at different hours of the day or night did not show any microfilariae. I was further advised to make a Kondoleon operation and to look for filariae in biopsy specimens. Milroy's disease, I think, can be excluded, as this case is unilateral. What other conditions would you consider? If filariasis, what would be the treatment? I read about injections with chenopodium oil. What is the dosage and where can it be obtained sterilized? Is there any authority in this country on this subject to whom I could write for information? Please omit name.

M.D., California.

Answer.—The case, as outlined, suggests two diagnostic possibilities: (1) filarial elephantiasis, and (2) congenital abnormality of lymph or venous efferents from the right leg and foot. The history of residence for the first six years of life in an endemic filarial district, with edema coming on at the end of this time, is strongly in favor of filarial origin. This origin having been twenty years ago, one would expect the adult filariae to have died long since. The patient has presumably not been exposed to reinfection during the past twenty years. One would therefore expect that organic damage originated in the customary manner in the period of active parasitization and that the appearance of organic lymph obstruction and elephantiasis was coincident with disappearance of live adult filariae and microfilariae in the circulating blood. Under such conditions the proper treatment is surgical, a modified Kondoleon operation being performed in an effort to divert the lymph drainage into the deeper channels around the great blood vessels. The operation should be preceded by one or two weeks of elevation and constant pressure. As a routine, thick blood smears should be made at two hourly intervals for twenty-four hours and searched thoroughly for microfilariae, in the remote possibility of their still being present. Drug treatment is useless. Roentgenograms of the soft tissues around, above and below the knee should be taken in two planes in the effort to demonstrate calcified adult filariae. If these are found, their surgical removal should be undertaken before Kondoleon drainage is attempted. O'Connor, Golden and Auchincloss (*Am. J. Roentgenol.* **23**:494 [May] 1930) have demonstrated the value of this procedure.

Endemic elephantiasis is seen occasionally with no exposure to filaria-bearing mosquitoes but can be reduced to terms of mechanical obstruction from trauma, masses, earlier phlebitis or cellulitis, or streptococcus infection.

DELAY IN SPEECH FUNCTION

To the Editor—What, if anything, can be done to develop the talking function of a child? The patient is a boy, aged 3 years, who seems to be normal in every way, with no defect of tongue, lips or vocal cords. He just does not talk. The grandparents are much worried.

Alvah Stone, M.D., Roanoke, Va.

Answer.—There are a number of factors which cause delay in development of speech. It is well known that a child who is congenitally deaf does not develop normally. In children in whom the function of hearing is diminished, the acquirement of speech is also delayed. It may be assumed that in some children there is delayed development of the speech center and association tracts There are also unexplained instances in which children learn to walk late and to talk the third or fourth year Ultimately, however, some of them prove to have high degrees of intelligence Not infrequently, boys in particular learn to talk as late as the third year, and sometimes the period of complete speech development lasts much longer The explanation of these cases is probably to be sought in a temporary inhibition of normal speech development In general, excluding the exceptions already noted, the onset of speech parallels the development of intelligence

So far as remedial treatment is concerned, if the child has normal hearing and intelligence, the ability to speak will develop spontaneously and naturally Attempts to force the child at an early age might cause mental overstimulation and nervousness If the child has a defect in hearing or intelligence, special methods of training should be begun later in childhood, when the nature of the defect is established

RECURRENT ECZEMA

To the Editor —Will you please advise me as to treatment of a skin condition in a man aged 55, who has a generalized itching, which is worse at night The condition has been present for about eight months and so far has failed to respond to every type of treatment used Physical examination revealed a normal state of nutrition and one or two carious teeth perhaps infected The skin was reddened and the rash was of a fine papular nature and seemed to be just beneath the epidermis The rash was more pronounced on the chest and upper extremity The condition has been diagnosed by one skin specialist as recurrent eczema The blood Wassermann test was negative on two examinations Urinalysis was negative Chemical examination of the blood revealed no abnormalities The treatment has been varied from the use of ointments containing salicylic acid, benzoic acid, tar ammoniated mercury, balsam of peru, sulphur precipitate calamine lotion camphor, menthol, phenol, and about every other antipruritic, to neoarsphenamine, iodides, metaphen and intramuscular injections of nonspecific proteins and intravenous treatment with mercury The diet has been regulated, one type of food at a time being omitted without noticeable results The patient s living habits have been checked The patient has been seen and treated by many different physicians including skin specialists, and to date his condition remains the same as when I first saw him about Aug 1, 1931 Please omit name

M D , Indiana

Answer —Assuming that the case is one of recurrent eczema, it would seem that the condition has probably been intensified by some of the applications and injections employed While stimulating applications are indicated in certain types of eczema, the condition described might be adversely affected by some of the agents used locally, particularly ammoniated mercury and precipitated sulphur, while the neoarsphenamine and mercury preparation employed intravenously might likewise have an undesirable effect

In a case of this type every effort should be made to discover external or internal factors, as outlined in any standard textbook on dermatology, that might be responsible for the eruption As a rule, a case of this type will do well with the use of so called colloid baths, such as oatmeal water to which sodium bicarbonate has been added Local applications should be bland, employing lotions or ointments or both The intravenous injection of sodium thiosulphate, as employed in the treatment of postarsenical exfoliative dermatitis is often of use in cases of this type

NEURITIS AND ARTHRITIS

To the Editor —I have a patient a dentist aged 27 who complains of pains resembling those of neuritis which are centered about the shoulders posteriorly, in the neck posteriorly and at times in the latissimus dorsi at about the level of the ninth and tenth ribs These pains are evidently precipitated by his work as they tend to pass off on days when he does not go to the office and are quite pronounced on his hard and long working days The areas are quite painful at night on his bad days A careful history and a physical examination do not suggest an etiologic agent to my satisfaction The erythrocytes number 4 660 000 leukocytes 7 000, the hemoglobin is 90 the urine is normal the Wassermann reaction is negative a prostatic smear is negative although about two years ago he had a urethritis with purulent discharge which was pronounced gonorrheal by a competent urologist Is there such a diagnosis or etiology as occupational neuritis ? As he gets no exercise I have advised a generous amount of exercise I should be grateful for any discussion you may make

M D Alabama

Answer —The diagnosis concerns brachial neuritis cervical arthritis, fibrositis and myositis The etiologic factors are postural, infectious, traumatic, exposure and metabolic Treatment includes removal of any foci of infection, especially in the teeth tonsils gastro intestinal and genito-urinary tracts, rest, avoidance of long continued strain, and physical therapy, including gentle massage radiant heat and diathermy any of these to be discontinued if they cause pain A support such as a cotton collar should be beneficial Patients with this condition should avoid drafts and cold air and should keep the tissues warm day and night Pure brachial neuritis is rare Symptomatic neuritis is due to arthritis of the cervical spine There is a type of brachial neuritis peculiar to drivers of automobiles in whom the attack usually affects the side next to the open window Some authorities state that diathermy and infrared rays are unsuccessful and that massage may be harmful Exposure to small doses of the roentgen ray for ten minutes twice a week for a month have been advised Radiant therapy has also been recommended

MULTIPLE THROMBI IN VESSELS OF LEGS

To the Editor —A man, aged 60, with moderate generalized arteriosclerosis, auricular fibrillation of at least three years duration, repeated blood pressure readings averaging 170 systolic and 90 diastolic, the urine showing one plus albumin and a moderate amount of casts, has had three attacks each of "cardiac indigestion," and thrombus formation in the lower limbs twice on the left and once on the right, during the past five years The last occlusion, which occurred twelve weeks ago, was the worst, and exhibited typical signs of femoral artery plugging, with absent popliteal pulsation, severe pain, coldness, cyanotic pallor of the leg and foot, and sensory and motor diminution Since then a gradual improvement has ensued, with residuals at this time consisting of cyanosis rubor on dependence, pain requiring a narcotic about twice daily, diminution of sensory apperception in the foot up to the ankle, and complete foot drop (paralysis of the anterior tibial muscle group) Treatment has embraced keeping the foot at right angles to the leg, massage, continuous heat and galvanic stimulation I have been informed that a chemical periarterial sympathectomy would benefit this condition The only reference available is the abstract in The Journal, Oct 3, 1931, pages 1039 1040 Reception of the details of this procedure would be appreciated especially the method and duration of application of the solutions whether or not a neutralizing solution is required, and the contraindications Any comment as to this treatment, or any other treatment for this possible Buerger s disease, will be appreciated Please omit name

M D , Michigan

Answer —It is not altogether certain from the history just what has really taken place The possibility that the arterial occlusion in each case was due to an embolus must be considered

Such an embolus might arise from a mildly active endocarditis, but five years is a long history for such a condition However, emboli can originate in a heart the seat of a very mild infection, or where no active infection can be proved Other sources are possible, as the loosening of small vegetations originating on plaques of the aorta

A thrombosis of the arteries on each of the occasions is also a possibility For some reason not known, such thromboses have been becoming more frequent during the past few years They are frequently associated with some mild infection or occur during convalescence, but they may occur suddenly without any proved cause

The case should be thoroughly reviewed with these two possibilities in mind, and especially with the view of ruling out an active infection of the heart

Buerger's disease would seem to be much less likely If it is present, any so called chemical periarterial sympathectomy would not be advisable at the time It is of unproved value and offers possibilities of danger It is just as well to wait and watch the results of such procedures on other physician's patients In a proved Buerger's disease, a ganglionectomy is often of value, but it would not be advisable in this case A great deal can be done in cases of Buerger s disease by giving the patient 4 or 5 liters of Ringer's solution daily, or by intravenous injections of a hypertonic salt solution, as 150 cc. of a 5 per cent solution every second day The purine base diuretics are of assistance in some cases Fever therapy is of value but should not be used in this case, nor should the hypertonic salt solution Theobromine in some form could be tried, as could the Ringer's solution starting with 1 or 2 liters and increasing the amount if tolerated well

TREATMENT OF SYPHILIS AND EXFOLIATIVE DERMATITIS

To the Editor —1 An ampule containing sodium dimethylarsenate $10\frac{8}{10}$ grains (0 7 Gm) and mercuric oxycyanide one twelfth grain (0 0006 Gm) in 5 cc of sterile water has been offered me for intravenous injection in the treatment of syphilis Please comment on its use 2 What is the method of hastening the clearing of exfoliative dermatitis after intravenous injection of neoarsphenamine? 3 Does mercury intravenously or cyanide 1 per cent 1 cc , produce exfoliative dermatitis, or does bismuth? Please omit name

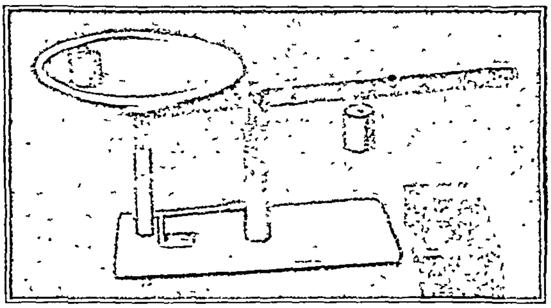
M D , California

Answer —1 Various combinations of sodium and arsenic are used in the treatment of syphilis When arsphenamine is neutralized with sodium hydroxide the disodium salt of arsphenamine (dihydrochloride of 3 diamine-4 dihydroxyarsenobenzene) is formed Sodium cacodylate (sodium dimethylarsenate) was at one time advocated for the treatment of early

SCALES FOR DIABETIC PATIENTS

To the Editor:—Charity patients in diabetic clinics seldom can afford to buy scales, yet weighed diets are conducive and at times indispensable to the treatment of diabetes. To supply this want, some of my patients in the diabetic section of the Falk Clinic, conducted by the University of Pittsburgh, constructed balance scales with metal picked out of the scrap piles, at the initial cost of 2½ cents. They are assembled by unemployed men and are calibrated to weigh within half a gram, by an expert, again unemployed.

A number of these scales were finished, as shown in the accompanying illustration, and distributed to deserving patients.



Balance for diabetic patients.

Beneficial results immediately became apparent, and in addition to the increased interest on the part of the entire group in their dietetic problems, patients were provided with an accurate means of weighing their total caloric intake regardless of their financial condition.

The social service department of the clinic has been requested to follow up those patients who have received such mechanical aids so that each set of scales will do maximum duty.

With the thought that others might wish to use this plan in solving similar problems, the matter is presented here.

J. West Mitchell, M.D., Sewickley, Pa.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

ENDOCARDITIS AFTER SCARLET FEVER

To the Editor:—In January of this year my son, aged 9 years, contracted scarlet fever. This left an endocarditis as a sequela. In spite of bed rest, a wholesome appetite and diet, and outward appearances of health, he persists in having a half degree of fever almost daily, and the systolic mitral lesion is gradually becoming more accentuated For two weeks following tonsillectomy his condition seemed aggravated, his temperature being elevated from 1 to 1.5 degrees, and his pulse was correspondingly accelerated. I have had him on salicylates, streptococcus vaccines, iron tonics and sun baths, but this low grade process continues in spite of all effort and his apparent well being. I will be pleased to learn of any more therapy you might recommend in this case. Please omit name.

M.D , Iowa.

Answer.—It is possible that the endocarditis described is the result of a complicating rheumatic fever. This is an important distinction to make because joint pains and rheumatic nodules may aid in determining the state of activity of the process. With either causation the child's weight curve at this stage of the disease would be a helpful index of activity or the nonexistence of the latter. As the query suggests, the temperature curve is important also; but this should be recorded in the absence of salicylates, to be significant. Even then it is difficult to interpret a fever of half a degree this long after the onset of the child's illness. Opinions may be had on both sides of this question, but many clinicians would favor disregarding this amount of fever in the absence of salicylate medication in a child of this age. An electrocardiograph tracing for evidences of disturbed conduction not detectable clinically in any other way would be of considerable significance, if positive.

If the boy is gaining a little in weight and shows no evidence of active rheumatic fever or of active endocarditis, other than the half degree of fever, and the electrocardiographic tracing is normal, discontinuation of medication and a gradual resumption of activity for the patient may be recommended. As Dr. Herrick and others have pointed out, physicians have sometimes erred in the past in making more of an invalid out of such a patient than the necessities of the case demand.

The existence of evidence of activity on any of the scores mentioned would justify the continuation of bed rest. Rest and good food and other general hygienic measures are the most valuable parts of therapy of the active stage. The value of other forms of treatment remains highly problematic. The salicylates are favored if joint involvement is present, and some believe in their use for the endocarditis itself.

FILARIASIS OR ABNORMAL LYMPH CHANNELS

To the Editor:—A woman, aged 26, a nullipara, has a large edema of the right foot ascending and diminishing in size till just below the knee. No discoloration, redness or pain is present, nor is there impaired arterial circulation. The Wassermann test is negative. Blood counts are normal. There is no x-ray evidence of a pathologic condition of the bone and no sign of tuberculosis The condition suggests a stasis in the lymphatics, although no enlarged lymph glands can be felt anywhere The swelling has existed since her childhood, about twenty years, but has increased during the last half year. Several years ago in France she received punctate cauterizations at the metatarsophalangeal joints. She states that these resulted in some benefit at the time. Up to her sixth year she lived in French Guiana, and afterward in France. I was advised to look for filariae. Blood smears taken at different hours of the day or night did not show any microfilariae. I was further advised to make a Kondoleon operation and to look for filariae in biopsy specimens. Milroy's disease, I think, can be excluded, as this case is unilateral What other conditions would you consider? If filariasis, what would be the treatment? I read about injections with chenopodium oil. What is the dosage and where can it be obtained sterilized? Is there any authority in this country on this subject to whom I could write for information? Please omit name.

M.D., California.

Answer.—The case, as outlined, suggests two diagnostic possibilities: (1) filarial elephantiasis, and (2) congenital abnormality of lymph or venous efferents from the right leg and foot. The history of residence for the first six years of life in an endemic filarial district, with edema coming on at the end of this time, is strongly in favor of filarial origin. This origin having been twenty years ago, one would expect the adult filariae to have died long since. The patient has presumably not been exposed to reinfection during the past twenty years. One would therefore expect that organic damage originated in the customary manner in the period of active parasitization and that the appearance of organic lymph obstruction and elephantiasis was coincident with disappearance of live adult filariae and microfilariae in the circulating blood. Under such conditions the proper treatment is surgical, a modified Kondoleon operation being performed in an effort to divert the lymph drainage into the deeper channels around the great blood vessels. The operation should be preceded by one or two weeks of elevation and constant pressure. As a routine, thick blood smears should be made at two hourly intervals for twenty-four hours and searched thoroughly for microfilariae, in the remote possibility of their still being present. Drug treatment is useless. Roentgenograms of the soft tissues around, above and below the knee should be taken in two planes in the effort to demonstrate calcified adult filariae. If these are found, their surgical removal should be undertaken before Kondoleon drainage is attempted. O'Connor, Golden and Auchincloss (*Am. J. Roentgenol.* 23:494 [May] 1930) have demonstrated the value of this procedure.

Endemic elephantiasis is seen occasionally with no exposure to filaria-bearing mosquitoes but can be reduced to terms of mechanical obstruction from trauma, masses, earlier phlebitis or cellulitis, or streptococcus infection.

DELAY IN SPEECH FUNCTION

To the Editor:—What, if anything, can be done to develop the talking function of a child? The patient is a boy, aged 3 years, who seems to be normal in every way, with no defect of tongue, lips or vocal cords. He just does not talk. The grandparents are much worried.

Alvah Stone, M.D., Roanoke, Va.

Answer.—There are a number of factors which cause delay in development of speech. It is well known that a child who is congenitally deaf does not develop normally. In children in whom the function of hearing is diminished, the acquirement of speech is also delayed. It may be assumed that in some children there is delayed development of the speech center and association tracts. There are also unexplained instances in which children learn to walk late and to talk the third or fourth year. Ultimately, however, some of them prove to have high degrees of intelligence. Not infrequently, boys in particular learn to talk as late as the third year, and sometimes the period of complete speech development lasts much longer. The explanation of these cases is probably to be sought in a temporary inhibition of normal speech development. In general, excluding the exceptions already noted, the onset of speech parallels the development of intelligence.

So far as remedial treatment is concerned, if the child has normal hearing and intelligence, the ability to speak will develop spontaneously and naturally. Attempts to force the child at an early age might cause mental overstimulation and nervousness. If the child has a defect in hearing or intelligence, special methods of training should be begun later in childhood, when the nature of the defect is established.

RECURRENT ECZEMA

To the Editor:—Will you please advise me as to treatment of a skin condition in a man, aged 55, who has a generalized itching, which is worse at night. The condition has been present for about eight months and so far has failed to respond to every type of treatment used. Physical examination revealed a normal state of nutrition and one or two carious teeth, perhaps infected. The skin was reddened and the rash was of a fine papular nature and seemed to be just beneath the epidermis. The rash was more pronounced on the chest and upper extremity. The condition has been diagnosed by one skin specialist as recurrent eczema. The blood Wassermann test was negative on two examinations. Urinalysis was negative. Chemical examination of the blood revealed no abnormalities. The treatment has been varied from the use of ointments containing salicylic acid, benzoic acid, tar, ammoniated mercury, balsam of peru, sulphur precipitate, calamine lotion, camphor, menthol, phenol, and about every other antipruritic, to neoarsphenamine, iodides, metaphen and intramuscular injections of nonspecific proteins and intravenous treatment with mercury. The diet has been regulated, one type of food at a time being omitted without noticeable results. The patient's living habits have been checked. The patient has been seen and treated by many different physicians, including skin specialists, and to date his condition remains the same as when I first saw him about Aug. 1, 1931. Please omit name.

M.D., Indiana.

Answer.—Assuming that the case is one of recurrent eczema, it would seem that the condition has probably been intensified by some of the applications and injections employed. While stimulating applications are indicated in certain types of eczema, the condition described might be adversely affected by some of the agents used locally, particularly ammoniated mercury and precipitated sulphur, while the neoarsphenamine and mercury preparation employed intravenously might likewise have an undesirable effect.

In a case of this type every effort should be made to discover external or internal factors, as outlined in any standard textbook on dermatology, that might be responsible for the eruption. As a rule, a case of this type will do well with the use of so called colloid baths, such as oatmeal water to which sodium bicarbonate has been added. Local applications should be bland, employing lotions or ointments or both. The intravenous injection of sodium thiosulphate, as employed in the treatment of post-arsenical exfoliative dermatitis, is often of use in cases of this type.

NEURITIS AND ARTHRITIS

To the Editor:—I have a patient, a dentist, aged 27, who complains of pains resembling those of neuritis which are centered about the shoulders posteriorly, in the neck posteriorly and at times in the latissimus dorsi at about the level of the ninth and tenth ribs. These pains are evidently precipitated by his work, as they tend to pass off on days when he does not go to the office and are quite pronounced on his hard and long working days. The areas are quite painful at night on his bad days. A careful history and a physical examination do not suggest an etiologic agent to my satisfaction. The erythrocytes number 4 660 000, leukocytes 7 000, the hemoglobin is 90, the urine is normal, the Wassermann reaction is negative, a prostatic smear is negative, although about two years ago he had a urethritis with purulent discharge, which was pronounced gonorrheal by a competent urologist. Is there such a diagnosis or etiology as "occupational neuritis"? As he gets no exercise, I have advised a generous amount of exercise. I should be grateful for any discussion you may make.

M.D., Alabama.

Answer.—The diagnosis concerns brachial neuritis, cervical arthritis, fibrositis and myositis. The etiologic factors are postural, infectious, traumatic, exposure and metabolic. Treatment includes removal of any foci of infection, especially in the teeth, tonsils, gastro-intestinal and genito-urinary tracts, rest, avoidance of long continued strain, and physical therapy, including gentle massage, radiant heat and diathermy, any of these to be discontinued if they cause pain. A support such as a cotton collar should be beneficial. Patients with this condition should avoid drafts and cold air and should keep the tissues warm day and night. Pure brachial neuritis is rare. Symptomatic neuritis is due to arthritis of the cervical spine. There is a type of brachial neuritis peculiar to drivers of automobiles, in whom the attack usually affects the side next to the open window. Some authorities state that diathermy and infra-red rays are unsuccessful and that massage may be harmful. Exposure to small doses of the roentgen ray for ten minutes twice a week for a month have been advised. Radiant therapy has also been recommended.

MULTIPLE THROMBI IN VESSELS OF LEGS

To the Editor:—A man, aged 60, with moderate generalized arteriosclerosis, auricular fibrillation of at least three years' duration, repeated blood pressure readings averaging 170 systolic and 90 diastolic, the urine showing one plus albumin and a moderate amount of casts, has had three attacks each of "cardiac indigestion" and thrombus formation in the lower limbs, twice on the left and once on the right, during the past five years. The last occlusion, which occurred twelve weeks ago, was the worst and exhibited typical signs of femoral artery plugging, with absent popliteal pulsation, severe pain, coldness, cyanotic pallor of the leg and foot, and sensory and motor diminution. Since then a gradual improvement has ensued, with residuals at this time consisting of cyanosis, rubor on dependence, pain requiring a narcotic about twice daily, diminution of sensory apperception in the foot up to the ankle, and complete foot drop (paralysis of the anterior tibial muscle group). Treatment has embraced keeping the foot at right angles to the leg, massage, continuous heat and galvanic stimulation. I have been informed that a chemical periarterial sympathectomy would benefit this condition. The only reference available is the abstract in The Journal, Oct. 3, 1931, pages 1039-1040. Reception of the details of this procedure would be appreciated, especially the method and duration of application of the solutions, whether or not a neutralizing solution is required, and the contraindications. Any comment as to this treatment, or any other treatment for this possible Buerger's disease will be appreciated. Please omit name.

M.D., Michigan.

Answer.—It is not altogether certain from the history just what has really taken place. The possibility that the arterial occlusion in each case was due to an embolus must be considered.

Such an embolus might arise from a mildly active endocarditis, but five years is a long history for such a condition. However, emboli can originate in a heart the seat of a very mild infection, or where no active infection can be proved. Other sources are possible, as the loosening of small vegetations originating on plaques of the aorta.

A thrombosis of the arteries on each of the occasions is also a possibility. For some reason not known, such thromboses have been becoming more frequent during the past few years. They are frequently associated with some mild infection or occur during convalescence, but they may occur suddenly without any proved cause.

The case should be thoroughly reviewed with these two possibilities in mind, and especially with the view of ruling out an active infection of the heart.

Buerger's disease would seem to be much less likely. If it is present, any so-called chemical periarterial sympathectomy would not be advisable at the time. It is of unproved value and offers possibilities of danger. It is just as well to wait and watch the results of such procedures on other physician's patients. In a proved Buerger's disease, a ganglionectomy is often of value, but it would not be advisable in this case. A great deal can be done in cases of Buerger's disease by giving the patient 4 or 5 liters of Ringer's solution daily, or by intravenous injections of a hypertonic salt solution, as 150 cc. of a 5 per cent solution every second day. The purine base diuretics are of assistance in some cases. Fever therapy is of value but should not be used in this case, nor should the hypertonic salt solution. Theobromine in some form could be tried, as could the Ringer's solution, starting with 1 or 2 liters and increasing the amount if tolerated well.

TREATMENT OF SYPHILIS AND EXFOLIATIVE DERMATITIS

To the Editor:—1. An ampule containing sodium dimethylarsenate $10\frac{8}{10}$ grains (0.7 Gm.) and mercuric oxycyanide one-twelfth grain (0.0006 Gm.) in 5 cc. of sterile water has been offered me for intravenous injection in the treatment of syphilis. Please comment on its use. 2. What is the method of hastening the clearing of exfoliative dermatitis after intravenous injection of neoarsphenamine? 3. Does mercury intravenously or cyanide 1 per cent, 1 cc., produce exfoliative dermatitis, or does bismuth? Please omit name.

M.D., California.

Answer.—1. Various combinations of sodium and arsenic are used in the treatment of syphilis. When arsphenamine is neutralized with sodium hydroxide, the disodium salt of arsphenamine (dihydrochloride of 3 diamine-4 dihydroxyarsenobenzene) is formed. Sodium cacodylate (sodium dimethylarsenate) was at one time advocated for the treatment of early syphilis but has been found inefficient and its use has been abandoned. The mixture of sodium dimethylarsenate with mercuric oxycyanide is another instance of a polypharmaceutic combination that offers no advantage in the treatment of syphilis. It is far better to use the standard method of administering arsphenamine or neoarsphenamine intravenously and mercury or bismuth compounds intramuscularly.

2. Exfoliative dermatitis after intravenous injection of neoarsphenamine will involute more rapidly when sodium thiosulphate in doses up to 1 Gm. is given intravenously.

3. Mercury compounds have in rare instances produced an exfoliative dermatitis. Pinard and Marassi (*Bull. et mém. Soc. méd. d. hôp. de Paris* **46:**1434 [Nov. 3] 1922) have reported an exfoliative dermatitis after intramuscular injections of bismuth compounds.

POSTINFLUENZAL PLEURAL EFFUSION

To the Editor:—A girl, aged 6 years, had influenza five weeks ago, followed by a right sided pleural exudation proved by roentgen examination, which I opened by intercostal paracentesis, with closed drainage under fluid. I emptied about 2 quarts at the time of the operation, which was done under local anesthesia, and there has been constant drainage since. Her temperature remained normal for about ten days and with decrease of drainage I tried to leave the tube out, but temperature ran up to 103 F., so I replaced the tube with abundant gauze to catch the discharge, which is yellowish green, sour-smelling pus. The temperature receded to normal again with occasional evening exacerbations to 99.4, returning to normal by morning. I changed the tube two days ago, yet the temperature comes up to 102 in the afternoon and down to near normal, 99.4, in the morning. Her appetite is only fair. The bowels are kept open with agarol I tempt her with a nourishing diet. I administer syrup of ferrous iodide 5 drops three times a day, and also a tonic of iron, quinine and strychnine, which I give to increase the appetite; I also give her viosterol and plenty of fresh air Within the last day or so there has developed a slight cough, not irritating or annoying, without expectoration. Could the tube cause this? She seems happy and comfortable and does not complain of any especial pain or soreness. I felt that the drainage tube should remain as long as a discharge persists and that the general tonics, food and fresh air as now outlined should be continued, but felt that perhaps something else could be suggested. Do you advise irrigating with surgical solution of chlorinated soda, as has been suggested by some? After three weeks, should the tube be removed and nature allowed to take care of the secretion? Would a mixed bacterin or serum be indicated or beneficial? The family is poor and had to remove the baby home after five days' hospitalization. Any suggestions will be gratefully received. Please omit name.

M.D., Oklahoma.

Answer.—A postinfluenzal pleural effusion in a child is usually pyogenic in origin, but a tuberculous pleuritis should be excluded if possible if the condition does not respond typically to adequate drainage. A Pirquet test is of value in case of a child. Demonstration of tubercle bacilli in the exudate is proof of a tuberculous infection, but failure to find them does not exclude this condition.

Adequate drainage is the first prerequisite to healing of an ordinary empyema and also of a tuberculous empyema secondarily infected with pyogenic organisms. Irrigation, preferably with surgical solution of chlorinated soda by the closed method or through a small open wound, is preferable to wide open drainage as long as the empyema cavity is of any size. It can be measured by filling it with saline solution and its extent can be visualized by means of a roentgenogram made with a 15 per cent sodium bromide contrast medium. Drainage should be such as to keep the cavity completely empty of pus all the time until it is obliterated.

General supportive measures as outlined are helpful, but complete continuous drainage is essential to a cure.

LOCAL ANESTHETIC FOR TYMPANIC PUNCTURE

To the Editor:—What is the most satisfactory local anesthetic to be used for tympanic puncture? Please omit name.

M.D., New Jersey.

Answer.—For some years, many otologists have used equal parts of cocaine, phenol and menthol instilled in the ear with a medicine dropper and allowed to flow against the tympanic membrane in order to give a local anesthesia. Others have used equal parts of phenol, menthol and oil of eucalyptus. It is doubtful whether the cocaine has much effect, because it does not seem to anesthetize through unbroken epithelium. The phenol and menthol, however, in concentrated solution, do have a benumbing effect on the epidermis. So far as we are aware, no local application gives a perfect anesthesia. Many years ago, Professor Neumann of Vienna suggested infiltrating the sensory nerves of the drum membrane with an injection of dilute procaine solution in the roof of the auditory canal in its inner third. The entrance of the needle is so painful that it probably is not preferable to a direct myringotomy without local anesthesia. A perfectly satisfactory local anesthesia for tympanic puncture is still to be sought. Whenever possible, the administration of general anesthesia is satisfactory and of short duration, especially if nitrous oxide or ethylene is employed.

USE OF CATHETERS IN CYSTITIS WITH PROSTATIC INFLAMMATION

To the Editor:—A man, aged 67, with a history of old gonococcal infection in youth, began with polyuria, and nycturia with strangury, three or four years ago. Cystoscopic examination revealed an atrophy of the prostate, and a retention catheter instead of suprapubic cystostomy was used for drainage on account of the surgical risk involved. Violent reactions occurred four or five days after, possibly urethral fever or renal crisis, and the patient was sent home a week later, having drained about two weeks. Catheterization (retention) was further instituted at home. This was stopped a day later on account of a purulent discharge due to a catheteral irritation. This catheter given the patient by the hospital was incidentally too hard and over a No. 16 French and probably was not changed for one week. At the present time the patient has strangury with concomitant loss of anal sphincteric control, and I am thinking seriously of resuming urethral catheterization either by the retention method or three times daily. Kindly state your opinion as to either method of catheterization in a subject with a guarded surgical risk. Does catheter irrigation through the urethra result in improvement of prostatic edema in hypertrophy as is shown by suprapubic drainage instituted at Mayo's? Does it give any benefit other than drainage by enlarging the lumen of the prostatic urethra in atrophy? If the patient's condition should improve, would a suprapubic cystotomy and fistula formation be advisable for drainage and lavage?

N. S. Giardina, M.D., Lorain, Ohio.

Answer.—The symptoms of polyuria, nycturia and strangury in a patient with obstruction of the bladder neck due to atrophy of the prostate would indicate that the urethral irritation caused by the indwelling catheter had extended to the bladder and produced a generalized cystitis in addition to the prostatic edema. The regular catheterization of the bladder and its irrigation once or twice a day with a warm solution of boric acid should prove more efficacious than the placing of a permanent catheter, the use of which had evidently instituted the previous irritation and would therefore probably not be well tolerated. A permanent catheter does not enlarge the urethral lumen but by its presence tends to produce edema, congestion and secondary infection.

Should the symptoms not improve after a course of regular bladder lavage, suprapubic cystostomy should be made. This need not prove a permanent fistula, for after the edema of the prostate has subsided the obstructing portion of the atrophic gland which originally initiated the train of symptoms from which the patient now suffers and is probably not of great size could be removed through the urethra either by the so-called punch operation or by one of the newer technics now commonly referred to as transurethral prostatic resection.

APOMORPHINE IN ECLAMPSIA

To the Editor:—A nonipara, five months pregnant, complained to her family, March 15, that she could not see and that her head ached badly. At midnight she had a convulsion and on examination showed a blood pressure of 225 systolic and 115 diastolic. Urine by catheter boiled solid, and the cervix was tightly closed. The patient was in a violent state at all times, making it necessary to give ether to examine her in any way and requiring two men to hold the arm still while a hypodermic injection was given. All the usual treatment was given her with the exception of evacuating the uterus, as dilating of the cervix was considered too big a procedure at that time. Morphine, barbital, magnesium sulphate by tube in the stomach, bleeding and other measures seemed of no avail and she had fourteen severe convulsions in eight hours. By this time she was in poor condition, the pulse was fast and thready, and it was evident to every one that a fatal termination was in prospect. A short time before, an article appeared in The Journal on strychnine poisoning treated by apomorphine with wonderful results. Owing to the great clinical similarity between strychnine poisoning and eclampsia, it was decided as a last resort to try the same thing in this case. She was therefore given one-fifth grain (13 mg.) of apomorphine by hypodermic injection. There seemed to be no evidence of nausea and within thirty minutes she was perfectly quiet. Two hours later she was given another tenth grain. After this there was some slight evidence of nausea but no vomiting. At this she broke out in a copious perspiration and seemed to be sleeping naturally and within the next two hours wet herself and the bed with urine. No further treatment was given, except hot packs, and the next morning she was conscious and gave her consent to the passage of a catheter to bring on labor. Her blood pressure was 190 systolic and 125 diastolic at this time, the urine boiling solid. She delivered a macerated five months' fetus the third day, and recovery has been uneventful. Did the apomorphine change the picture as it does in strychnine poisoning? Please omit name.

M.D., Utah.

Answer.—The case report on the use of apomorphine against eclamptic convulsions appears quite interesting. The prompt quieting of the patient within thirty minutes after the administration of the first dose of the apomorphine indicates that this was more than a coincidence. It harmonizes with the sedative action of apomorphine in other convulsive conditions, ranging from hysteria and alcoholic delirium to heat cramps and strychnine poisoning. Several cases of the latter were reported in the paper of Haggard and Greenberg (The Journal, April 2, p. 1133), to which the correspondent evidently refers. The mechanism of this antispasmodic action is not understood and its efficacy against strychnine is rather limited; but it may well deserve further trial. The dosage should not exceed that mentioned by the correspondent, one-fifth grain (13 mg.), for the first injection, followed, if necessary, by one-tenth grain (6.5 mg.) in one or two hours.

OPACITY OF CORNEA

To the Editor:—Please give me advice on the following case: A man, aged 38, had an operation on the right eye for certain congenital weakness of the eyesight about fourteen years ago, in which the lens is said to have been removed. Although the sight of that eye was much improved by the operation, he occasionally suffered from "corneitis," and about four years later he resorted by himself to an unwarranted application of an electric (galvanic?) current and suffered from violent headache throughout the night and completely and permanently lost the sight of that eye in the morning. His case was then diagnosed as acute glaucoma. Two years later he contracted an infection and the opacity of the diseased eye became markedly increased. At present there is dense opacity limited within the cornea, through which small portions of clear pupil and iris can be seen. The patient is neurasthenic because of the bad looking eye. The left eye is quite normal and has had no trouble. Will you kindly discuss the general way of treating the cornea opacity for cosmetic purposes? Is there any simple method of camouflaging the leukoma as by painting, other than by removal of the scar tissue or tattooing? Please omit name.

M.D., New York.

Answer.—It is to be regretted, but the patient does not stand much chance of improvement in the appearance of the offending cornea except by some radical procedure. An endeavor to excise the scar surgically would probably make matters worse. Tattooing offers somewhat better chances of cosmetic improvement. If the eye is hopelessly blind, one may advise exenteration with fat implantation into the scleral cavity and subsequent use of a shell eye.

CALCIUM THERAPY

To the Editor:—I am rather at sea regarding certain aspects of calcium therapy. Will you kindly answer the following questions: 1. Does it matter which salt of calcium one uses in attempting to raise the blood-clotting time? 2. Is there any advantage in giving calcium intravenously or intramuscularly, rather than by mouth, except when there is a gastro-intestinal disturbance? Are there conditions in which one can with any certainty say that calcium given as food or by oral medication is not absorbed? 3. Is there any advantage in giving calcium salts for nutritional purposes when the patient is taking an adequate quantity of milk or other calcium-containing foods? 4. Is there any peculiar advantage in the use of calcium gluconate (which one sees advertised much) over the other salts, other than its adaptability for hypodermic administration? In particular, has it any exceptional value in infantile tetany? 5. Has calcium a helpful action in catarrhal infections, or toxic jaundice? Kindly omit name.

M.D., Michigan.

Answer.—1. No.

2. In emergencies, as well as in spasmophilic conditions, intravenous injection may be more rapidly efficient. The details of calcium absorption are not sufficiently understood to pronounce with certainty as to when, under ordinary conditions of life or disease, it will not be absorbed.

3. No.
4. No.
5. No.

HEADACHE AFTER LUMBAR PUNCTURE

To the Editor:—A man, aged 32, had a lumbar puncture early in January for a spinal Wassermann test. This, and the blood test, were found negative. The following day the patient had a severe headache at the back of the neck and the top of the head. As this headache was not relieved in any other way but by lying down, he stayed in bed a month. The headache, which was attributed to a slow leakage of the spinal fluid, improved gradually but still is present each day, sometimes becoming quite severe, the pain being identical with the pain that came on after the puncture. Previous to the lumbar puncture the patient rarely had a headache. He is inclined to be high strung but not neurotic and is in good general health. In the early stage pituitary extract was used, also dextrose solution intravenously. These had only a brief trial. The headache has continued so long that I am at a loss to know whether it can still be due to lack of pressure of the spinal fluid. I should be glad to have a method of treatment suggested. Please omit name.

M.D., Pennsylvania.

Answer.—The protracted headache that is described is probably not due to persistent leakage of the spinal fluid. It is probably a functional headache in a neurotic individual. The reason for the lumbar puncture was not given. It is, of course, possible that the fundamental process for which the spinal puncture was done may be at the basis of the headache.

CUTTING HAIR AND PREMATURE GRAYING

To the Editor:—In the May 14 issue of The Journal a query is made regarding the effect of cutting the hair. It is answered that it "has no effect whatever," and that hair "grows only from the papilla at its base, a separate structure." What, then, accounts for the fact that hair will grow only to a certain length, and that, when cut, it immediately resumes growth until it has again reached that particular length? Doesn't this show the presence of a link between the papilla and the shaft? Does the recent literature give any explanation for premature graying, such as occurs in otherwise perfectly normal and healthy young adults? Please omit name.

M.D., New Jersey.

Answer.—No one will deny "the presence of a link between the papilla and the shaft." The papilla produces the hair, is connected to it during the whole of its time of service, nourishes it and regulates its growth, but at last separates from it, the hair falling out, the papilla remaining in the skin. When cut, the hair regrows, if allowed, to its normal length, because nature insists on hair of a certain length for each individual. The stimulus reaching the papilla must be the change in tension resulting from loss of weight of the hair. Cutting all the hairs does make them grow, but only to their regular length, and does not increase their number. There has been no recent contribution on premature graying.

NO SCARLET FEVER TOXOID

To the Editor.—Will you please inform me where I can get information about a product for the active immunization against scarlet fever which has been developed along the lines of diphtheria toxoid; namely, with solution of formaldehyde as a detoxifying agent. My attention was called to this product in the magazine *Time*, issue of April 11, 1932, under the section of medicine, where the product was described as the discovery of the National Institute of Health. Can you tell me something about this institute and its standing? Please omit name.

M.D., Illinois.

Answer.—The addition of formaldehyde to diphtheria toxin detoxifies the preparation, with the production of a toxoid that retains antigenic or immunizing properties. But it has not been demonstrated that such partial detoxification as results from the addition of formaldehyde to scarlet fever toxin is associated with the production of a scarlet fever toxoid. The best evidence thus far available is to the contrary. Until the existence of a scarlet fever toxoid capable of producing satisfactory immunity is demonstrated, it is inadvisable that preparations claiming to be scarlet fever toxoid be placed on the market, particularly in view of the failure of the "ricinoleated" scarlet fever preparations, for which similar claims were made.

The National Institute of Health is the name now applied to the Hygienic Laboratory of the United States Public Health Service, which has been authorized to conduct research and to receive funds for this purpose.

OINTMENT FOR INFLAMMATION UNDER FORESKIN

To the Editor:—Please advise me whether or not the repeated and prolonged use of an ointment consisting of 1 per cent of yellow mercuric oxide with 2 grains of menthol to the ounce, applied underneath the foreskin in the treatment of smegma and inflammation, is harmful either locally or constitutionally. Would it cause any ill effects either locally or constitutionally in the female, as this medication is transmitted repeatedly during coitus? Please omit name.

M.D., New York.

Answer.—The repeated and prolonged use of yellow mercuric oxide with menthol for the treatment of smegma and inflammation underneath the foreskin is hardly desirable. If the patient has a condition that demands repeated and prolonged local treatment, a circumcision is the simple way out. If the patient does not wish to have a circumcision, dusting powders are indicated. A mixture of equal parts of bismuth subgallate and talcum powder does not produce irritation and is more efficacious.

COLD, CLAMMY, PERSPIRING HANDS

To the Editor:—Under what conditions does one find cold, clammy, perspiring hands? Numerous pupils in my conference groups ask this question. An early reply would be greatly appreciated.

Lucile Spire Blachly, M.D., Weatherford, Okla.

Answer.—The most characteristic type of functional circulatory disturbance resulting in cold perspiring hands is also associated with varying degrees of color change. It is called acrocyanosis. The hands and less often the feet are a red-blue, often somewhat puffy, always cold and moist. The color change is often sharply demarcated above the wrist. There may be no other symptoms, and the individual may seem to be in good health.

This condition appears more often in women than in men, and when in males most frequently at puberty or shortly afterward or associated with effort syndrome It may be one of the features of hypothyroidism, never in hyperthyroidism, in which the hands are moist, red and warm It is a vasomotor neurosis and may occur in association with other neuroses It has been described (Lavani) as occurring in endocrine disorders other than hypothyroidism, especially ovarian dysfunction

Lewis believes that the disorder is one of arteriolar function with angiospasm and capillary anoxemia Lavani and others consider it to be a stasis in the venous side of the capillary circulation with dilatation of the venules

This condition, or *variations of it, may follow on debilitating* illness or even acute infections and occurs commonly in chronic arthritis

Other types of functional circulatory disorders in which pallor is the principal color reaction may fall into the Raynaud disease group, of which there are also variations These may occur in apparently healthy individuals or in association with neurosis

ASTRINGENT RECTAL SUPPOSITORY

To the Editor —Will you kindly supply me with a formula for a good rectal suppository to be used principally as an astringent There is one such on the market a proprietary product and I do not care to use it if I am able to substitute another

W E Scribner M D New York

Answer —The following formula would probably meet the requirements and have the advantage over the proprietary product that it is actually and definitely astringent and that its astringency can be readily modified by changing the proportion of tannic acid

Tannic acid	1 0 Gm
Balsam of peru	1 5 Gm
Bismuth subnitrat	10 0 Gm
Cacao butter	17 0 Gm
Cerate	2 0 Gm

Mix and divide into ten suppositories
Label One three times a day

“BARBOTAGE IN SPINAL ANESTHESIA

To the Editor —Kindly explain just what Labat means by the word ‘barbotage He says, *injection with or without barbotage* Would there be any objection in using an ephedrine procaine ampule for injecting the skin and interspinal ligament before proceeding to the use of French neocaine as is recommended in the spinocaine technic? Which do you think would be the simpler and safer method (spinal) to be used in a small hospital where the responsibility of the anesthetic rests pretty much on the surgeon? I mean which would be the simpler and safer to use, neocaine or spinocaine Please omit name and address

M D North Dakota

Answer —“Barbotage’ is defined in the American Illustrated Medical Dictionary as Fillestre s method of spinal anesthesia in which the needle is inserted into the sacrolumbar space, and after the injection the piston of the syringe is moved to and fro several times’ Commonly, however, barbotage refers merely *to the to and fro motion of the piston during the injection by* which fluid is alternately injected and aspirated Injection without barbotage is made when after injection is once started, the syringe is emptied without further aspiration There is no objection to the use of an ephedrine-procaine hydrochloride solution for infiltration before spinal anesthesia with procaine hydrochloride except in hypertensive patients In these cases the ephedrine should be administered after injection when there is assurance that the procaine has been deposited in the spinal fluid Procaine hydrochloride would be more satisfactory than “Spinocaine’ in the circumstances mentioned

TREATMENT OF SYPHILIS

To the Editor —Sept 15 1931 a man aged 32 first noticed a rash *over the entire* body and complained of sore throat A Wassermann test taken on that date was positive The date of exposure was about Aug 1 1931 No chancre was noticed but there was a swelling of the glans penis, August 11 I assume that he did have an interurethral chancre September 18, treatment was started and he received twelve intravenous injections of neoarsphenamine 0 6 Gm and fifteen 1 cc intramuscular *injections* of potassium bismuth tartrate the course ending on Jan 1 1932 At this time a Wassermann test was taken and proved to be negative January 28 another Wassermann test was taken, which was also negative. The second course extending from January 28 until April 16, included twelve intravenous injections of neoarsphenamine 0 6 Gm., and twelve 1 cc. intramuscular injections of potassium bismuth tartrate I am planning to take another Wassermann test, May 15 Should this next test be negative what would be the treatment, if any, after that? Please omit name

M D, Massachusetts

Answer —The amount of treatment advised by various authorities in the treatment of early syphilis shows great diversity, although all are agreed that adequate treatment administered as early as possible is necessary for a cure If treatment is discontinued at the end of six months in spite of a negative Wassermann reaction there is a possible danger of relapse Two additional somewhat shorter courses of six to eight weeks' duration with one of the arsphenamines and bismuth or mercury compounds should be given A spinal fluid examination should also be done in one of the rest periods

Council on Medical Education and Hospitals

COMING EXAMINATIONS

American Board for Ophthalmic Examinations Montreal, Sept 19 Sec Dr William H Wilder, 122 S Michigan Ave, Chicago

Book Notices

The Costs of Medicines: The Manufacture and Distribution of Drugs and Medicines in the United States and the Services of Pharmacy in Medical Care. By C. Rufus Rorem, Ph.D., C.P.A., and Robert P. Fischelis, B.S., Phar.D. Publications of the Committee on the Costs of Medical Care, No. 11. Cloth. Price, $2.50. Pp. 250. Chicago: University of Chicago Press, 1932.

The American people spend approximately $715,000,000 *a* year for drugs and medicines. Of this amount $190,000,000 represents drugs prescribed or dispensed by physicians, $165,000,000 home remedies, and the remaining $360,000,000 represents "patent medicines." It would seem to be reasonable to believe that at least 80 per cent of the last mentioned item constitutes money that is wasted. Perhaps the use of the "patent medicines" results in serious harm because of dependence on them by those who should be receiving scientific diagnosis and treatment. The data here brought out are of great significance in estimating the manner in which money spent for medical care is being distributed. Incidentally, the investigators find that the same public is spending some $300,000,000 annually for toilet goods.

The volume on this subject issued by the Committee on the Costs of Medical Care presents an excellent analysis of the profession of pharmacy and its growth, a consideration of the way in which the pharmacy has been modified by the introduction of other lines of trade, and a consideration of the chain store in the pharmacy field and of manufactures of various types of pharmaceuticals.

A chapter on avertising and promotion of both ethical and quack products affords a remarkable insight into current methods of promotion. In the summary and conclusions to the volume it is brought out that the manufacture and sale of products with secret formulas are inconsistent with lowered costs of medical care, and that the annual bill for medicines in the United States is unnecessarily high. It is also considered an incongruity that the medical profession should follow rigorous codes of ethics in promoting their services, whereas the manufacturers and distributers of medicine utilize all types of merchandising methods for their promotion.

It is considered that federal and state laws controlling manufacture and distribution of medicines are inadequate. The authors recommend better education of the public as to the use of suitable home remedies and the abolition of secret formula drugs and medicine through compulsory disclosure on labels and compulsory operation under annual license of all manufacturers of drugs and medicines.

Elektrische Verletzungen: Klinik und Histopathologie. Von Dr. Stefan Jellinek, a. o. Professor der Elektropathologie an der Universität in Wien. Paper. Price, 42 marks. Pp. 340, with 215 illustrations. Leipzig: Johann Ambrosius Barth, 1932.

The increasing practical use of electricity has led to the development of a new branch of medicine; namely, electropathology. Jellinek's book is *noteworthy* as a *pioneer*, systematic presentation of the clinical phenomena and the pathologic anatomy of electrical injuries. The book is the product of thirty years of active clinical experience and study of electropathology in cooperation with clinicians and investigators in the Allgemeines Krankenhaus in Vienna. A brief summary of the contents will indicate the scope of the book. The first chapter deals with electrical trauma and the various factors concerned in its production under various conditions. Then the subjective sensations and the immediate objective symptoms of the victims of electrical injury are discussed. Next comes detailed description of electrical changes in the covering of the body: the mark of the current (*strommarke*), electromechanical injury, the electrical burn, mixed forms, metallization, electrochemical changes, edema, impressions, lightning figures, and the immediate electrical necrosis. This part is illustrated by fifty telling illustrations, many in colors. Now follows consideration of severe external electrical injuries, the general aspects, including bacteriology, cranial injuries and injuries of the extremities and the trunk. This part also is well illustrated. The morbid conditions produced in the internal organs and the nervous system by electricity are considered in two chapters. The gross and microscopic anatomy of electrical trauma is described in two well illustrated chapters. The final chapter is devoted to treatment. The imperative necessity of prolonged artificial respiration (Silvester's method preferred) in cases of apparent death from electrical shock is emphasized. If the efforts are not successful after twenty minutes, withdrawal of enough spinal fluid by lumbar puncture to reduce the pressure to normal is urged. The value is stressed of the benzine compress, carefully applied, as a heart stimulant and in external electrical injury. But this is not *the place to discuss* details of treatment. The book is a contribution of major significance to electropathology and it should be translated into English.

Essentials of Psychiatry. By George W. Henry, A.B., M.D., Assistant Professor of Psychiatry, Cornell Medical School, New York. With a chapter on Psychiatric Nursing. By Adele Poston, R.N. Second edition. Cloth. Price, $4. Pp. 304. Baltimore: Williams & Wilkins Company, 1931.

In the comparatively small bulk of this volume the author has endeavored to present not only descriptions and case reports of the psychoses and psychoneuroses and their treatment but also personality development, child guidance, mental hygiene, psychopathology of the normal, the various forms of psychoanalysis and, in addition, psychiatric nursing and social service. The natural consequence is that the presentation is summary and dogmatic and tends to make the problems appear far more simple than they really are. The material is carefully selected and formally sound and has been put together in probably as good a form as is possible in view of the enormous ground covered. The danger is that it will leave the impression with the reader that he knows all there is to know about psychiatry. The author evidently recognizes the danger of oversimplicity and in the introduction cautions the reader to make use of the references given to the literature, though it appears from looking through them that they refer in the majority to strictly psychoanalytic literature.

Undersökningar över främre hornhinneytans form. Akademisk Avhandling *som med tillstånd av vitterfarna medicinska fakulteten i Uppsala för* vinnande av medicinsk doktorsgrad till offentlig granskning framställes. Av. Fredrik Berg, Med. Lic. å Fysiologiska Institutionens Lärosal Lördagen den 16 Mars 1929 Kl. 10 F. M. [Investigations Concerning the Outer Surface Form of the Cornea. An Academic Dissertation Which, With the Permission of the Advanced Medical Faculty at Uppsala University, is Presented by Fredrik Berg, Medical Licentiate, at a Public Examination for the Object of Winning his M.D. at the Examination Hall of the Institute of Physiology—Saturday March 16, 1929 at 10 A. M.] Paper. Pp. 189, with 92 illustrations. Göteborg: Elander, 1929.

The purpose of this research is to establish as accurately as possible the curvature of the anterior surface of the cornea and its variations in different states of refraction and in varying sizes and shapes of the eye itself. The work is based on the examination of 130 normal eyes, two cases (four eyes) of microphthalmia, one case (two eyes) of microcornea, and five cases of megalocornea. In conducting the investigation, the *principle of measuring* the corneal reflexes from mires of known dimensions was followed and two methods were used: one by means of a modified Javal-Schiøtz ophthalmometer and the other by the photographic method of Gullstrand. Both methods are open to minor errors, but the nature of the errors in one case is entirely different from that in the other.

The previous conceptions of the shape of the cornea, as formulated by Gullstrand and others, are that the central area of the cornea, approximately 4 to 5 mm. in diameter, is essentially spherical; that the central spherical area is displaced somewhat temporally and downward from the visual axis; that from this area toward the periphery the curve flattens, and that the flattening of the curve is more marked nasally and above than temporally and below. The author finds these conceptions essentially correct.

The curve of the horizontal meridian, in eyes in which the central refraction and in which the dimensions of the eyes fall within normal limits, proves to be remarkably symmetrical and constant. The horizontal curve, therefore, is used mainly in this work in recording comparisons in different conditions. The vertical meridian, on the other hand, shows wide variations and irregular curves.

The author goes at some length into the phenomenon of a line which Handmann had observed during transillumination of the eyeball and first described in 1923. Handmann designates it as a fine, refractive line running in an oblique horizontal direction through the upper half of the cornea Berg investigated 100 consecutive cases of otherwise normal eyes and demonstrated Handmann's line, not only by transillumination but also by skiascopy, in twenty-one cases Corresponding to this line, he discovered a sudden flattening of the corneal curve at about 15 to 20 degrees above the horizontal meridian This flattening followed roughly the location of the edge of the upper lid In all these cases there existed an increased pressure on the eyeball either from such conditions as blepharospasm, or from a thick and heavy upper lid He concludes, therefore, that Handmann's line is the result of an abnormal pressure of the upper lid on the cornea

In cases in which the normal proportions of the bulbus are disturbed, as in microphthalmia, microcornea, megalophthalmia and megalocornea, the corneal curves do not follow those of the normal eye The difference manifests itself mainly in a contraction or an expansion of the central spherical area The peripheral flattened zone is much less affected as to both shape and extent In microphthalmia and in microcornea the central spherical area is partly or entirely absent The peripheral flattening on one side meets that on the other side in the center of the cornea This offers an explanation for the high degree of hyperopia that often accompanies a pure microphthalmia In megalocornea the increase in area is taken up nearly altogether by an enlargement of the central spherical area

The work bears evidence of extensive and careful study of the field, including the numerous mathematical considerations that enter into the subject The only criticism that could be brought against it would be that the conclusions are based on the study of a rather small number of cases

The Cost of Equipping a Dental Office A Study of the Initial Expenditures of Dental Graduates When Equipping an Office for Practice By Dorothy Fahs Beck of the Research Staff of the Committee on the Study of Dental Practice of the American Dental Association Publications of the Committee on the Study of Dental Practice of the American Dental Association No 2 Paper Pp 11 Chicago University of Chicago Press 1932

The data on which this study is based consist of information from two independent sources namely replies of dental graduates of 1930 to a schedule sent them by mail, and information furnished by dental supply houses regarding the purchases in 1929 of recent dental graduates Schedules sufficiently completed for use in the study were received from 512 graduates of 1930 The information received from nine dental supply houses furnished data on 236 purchases

The mean initial expenditure for operating room and laboratory equipment of 480 dental graduates of 1930 was $2 340 The mean intial expenditure for the same item of forty-one dentists who specified second-hand equipment was $1,515, or somewhat more than $800 below that for the total group A comparison of these figures with the data from the dental supply houses shows that the mean initial expenditures of 236 purchases reported by individual dental supply houses for 1929 was $2 109, or about $230 less than the amount reported directly from 480 dentists Table 3 is interesting because of the percentage of analysis of the various articles of equipment purchased by 500 dental graduates of 1930 (these articles were purchased prior to 1931) Of the 500 dentists, 100 per cent purchased a dental chair 99 per cent a cabinet 97 per cent, a sterilizer 95 per cent a dental unit 90 per cent a dental light 88 per cent, an electric engine 69 per cent, casting equipment, 65 per cent, an electric lathe 52 per cent a laboratory bench, 49 per cent, an air compressor, 46 per cent, x-ray equipment, 8 per cent, a gas machine, 4 per cent, a safe This analysis does not necessarily include all articles of purchase but is merely an analysis of those items asked for on the schedule used in the study

It appears from this study that the mean initial expenditures for dental supplies of 486 dental graduates of 1930 was $187, and the mean initial expenditures for reception room furnishings of 496 dentists of the same year of graduates, $139 In some instances it was found necessary for dentists to expend a certain amount for additional plumbing and wiring of their offices The mean initial expenditure for this item is given at $162

The average of these total expenditures is $2 867 This includes an average for miscellaneous items of $66 In percentages, this may be summarized as follows dental equipment, 80 7 per cent, supplies, 6 5 per cent, plumbing and wiring, 5 7 per cent, reception room furnishings, 4 8 per cent, miscellaneous, 2 3 per cent

It appears that those dentists who were beginning to practice in towns of medium size spent on the average more for their office equipment than those locating in small towns or large cities

Although this analysis does not purport to include all factors that are involved in the equipment for dental practice, the data presented should provide a helpful guide to those who are about to enter the practice of dentistry.

La syringobulbie Contribution a la physiopathologie du tronc cerébral Par N Ionesco Sisesti Preface du Professeur Georges Guillain Paper Price 70 francs Pp 391, with 28 illustrations Paris Masson & Cie 1932

Cavities occurring in the spinal cord and known as syringomyelia may arise also in the medulla, when they are termed syringobulbia They may form in the medulla secondarily, by extending from the spinal cord, or may originate there primarily As they are located in a comparatively small area, where the majority of the cranial nerves essential to life originate, the clinical pictures of syringobulbia of necessity vary greatly On the other hand, the cavities may cause only a small destruction of the medulla, of one nucleus or of one of the numerous pathways connecting the medulla with the neighboring organs Such lesions cannot be produced experimentally, and to have an opportunity to study the changes produced by such natural experiments is a great privilege Jonesco-Sisesti followed up eleven personal cases of syringobulbia, four of them pathologically in serial sections all with the method of Weigert-Pal counterstained with carmine, in one case an Alzheimer method was used also In addition, he gathered a hundred cases from the literature Probably a more thorough study with histopathologic methods of the four cases of cavities in the medulla would have led the author to the conclusion that syringomyelia or syringobulbia is not identical with a gliomatous growth and that neither is an infectious disease Probably it would have shown also why there is sometimes lack of correspondence between the extent of the anatomic changes and the clinical picture, which may be insignificant in the presence of vast anatomic changes Otherwise, the difficult and seemingly dry subject is covered admirably, in an entertaining and lucid manner The clinical and anatomophysiologic facts are carefully studied, analyzed and correlated It is an exceptionally able review of the modern status of the anatomy and physiology of the cranial nerves, their nuclei and tracts It is the best and most comprehensive treatise on the subject since the famous monograph of Schlesinger of thirty years ago In an extensive treatise like this with a bibliography of 460 references, mistakes are unavoidable Onuf and Collins for instance well known American neurologists, are referred to as British Dejerine is spelled Dejerine, and Argyll Robertson is spelled Argyll-Robertson

The Anthropometry of the American Negro By Melville J Herskovits Cloth Price $4 Pp 283 with 31 illustrations New York Columbia University Press 1930

The American Negro today is not the American Negro of Revolutionary or Civil War days In this volume the author, as the result of four years of research presents a picture of what has developed from the American Negro through long continued mixture with the white population and the aboriginal American Indian types Twenty-nine per cent of the Negroes examined claimed to have partial Indian ancestry and the anthropometric studies seemed to confirm the validity of this claim The type toward which the American Negro in this country seems to be evolving is a relatively homogeneous one The current customs among the American Negro populations bearing on the invidious nature of light color seem to make for a strong tendency toward marriage between dark men and light women and thus to set up a social mechanism which, if continued will intensify Negroid features for this type in the future The studies of Herskovits incline him to the belief that the amount of racial mixture represented in the American Negro population as a whole shows that the census estimate of 85 per cent pure Negro is not correct

Die Nervenkrankheiten des Kindesalters. Von Professor Dr. Georg Peritz Second edition. Paper. Price, 39.50 marks. Pp. 688, with 178 illustrations Leipzig: Fischers medizinische Buchhandlung, 1932.

This book, the first edition of which appeared twenty years ago, has been completely rewritten. In the lapse of years, knowledge of the nervous diseases of children has increased and several diseases have been described and studied which were unknown when the previous edition was published. The author attempts to justify the teachings of Freud, but he does not think that the freudian treatment is applicable to nervous children. The subject matter is divided into two parts, the general and the special. In the first division he considers in detail the nervous structures of childhood, general symptomatology, the autonomic nervous system, speech disturbances, examination of the spinal fluid, roentgen examination of the skull, ventriculography, and the microscopic study of the skin capillaries. A tabular form is given for psychologic examination, with minute details for determination of the mental status. In the special portion of the book he discusses the usual organic nervous diseases, as well as the diseases of the endocrine system. Chapters on the neuroses and the psychopathic diseases of childhood are included. The author notes that, in infantile cerebral palsy, birth trauma should be considered only one of the factors in the etiology and that the hemiplegic forms are more often the result of infection, while birth trauma contributes a considerable part in the production of the diplegic forms. Nevertheless, syphilis, postpartum trauma and brain malformation associated with malformation in other organs are contributing factors, in some cases at least. The chapter on encephalitis is well presented, and the postvaccinal variety is considered in some detail. Peritz believes that this condition is caused by an extraneous virus in the vaccine. Syphilitic disorders of the nervous system receive important and detailed consideration, together with minute directions for treatment. In discussing epilepsy the author considers the various theories concerning the etiology and pathology and comes to the conclusion that the disorder is not due to physiochemical, anatomic or physiologic causes but to a vascular circulatory disturbance. In other words, he believes that an angiospastic spasmophilic constitution is the basis for epilepsy. This is a splendid compendium of our knowledge on the nervous and mental disorders of infants and children, and it will be eagerly consulted by those who seek authoritative information.

The Healing Cults. A Study of Sectarian Medical Practice: Its Extent, Causes and Control. By Louis S. Reed, Ph D Publications of the Committee on the Costs of Medical Care, No. 16. Cloth. Price, $2. Pp. 134 Chicago: University of Chicago Press, 1932.

Many of the studies made by the Committee on the Costs of Medical Care may have seemed to physicians to be somewhat remote from any immediately practical service to the public. Such questions cannot, however, arise in relationship to the present volume. Here, unquestionably, is the most accurately assembled data thus far made available on sectarian practice. Dr. Reed points out that there are some 36,000 cult healers in the United States, including osteopaths, chiropractors, naturopaths, manipulative and physical therapeutic healers of all types, and the numerous offshoots of Christian science and faith healing. For the worse than useless services of this remarkable group, the American people pay each year $125,000,000. When it is considered that this sum represents more money than is spent altogether for preventive medicine, a realization of what such waste means to the public begins to develop. The book is crammed with facts. Reed considers the distribution and economic importance, the history, the legal regulation and the medical relations of each one of the cults discussed. He lists the available schools and provides data as to numbers of men in practice and the amounts that they earn. The concluding chapter deals with the causes and control of medical sectarianism. It is found that the cultists flock to large population centers more than do physicians, that practically all of them except Christian science are peculiar to America, that none of the cults have any permanence, and that they have no proper or logical place in medical care. The psychology of cultist practice seems to be quite thoroughly understood by Dr. Reed. The basis of their existence is the failure of the public to understand scientific medicine; the relationships of physicians; their significance in the social, economic and scientific plan of things, and the long and arduous preparation actually necessary for medical practice. Dr. Reed considers what the law may do to control sectarian practice and comes eventually to emphasis on basic science laws and a minimum standard of education for all who propose to heal the sick.

Handbook of Medicine for Final Year Students. By G F Walker, M D, M R C P, Consulting Physician to the Sunderland Municipal Hospital, Leeds Cloth. Price, 10s 6d Pp 255 London John Bale, Sons & Danielsson, Ltd., 1931.

A careful perusal of this little volume, subsequent to an unfavorable prejudice gained by reading the introductory note, completely substantiates the author's claims. Following is an abstract of the introductory note:

> The author of this book ventures to claim for it a high degree of utility and originality. It is intended to serve several classes of students of medicine. First, the serious student in his clinical years taking the ordinary course for degree or license who wishes to know the topics and problems on which he should concentrate Second the student who has perhaps been disheartened by the difficulties and complexities of medical study and who wishes in a few months or weeks prior to his "final" to turn to something fresh and practical which has been almost specifically written for him Third the newly qualified practitioner about to embark on hospital or assistantship duties and who wants some pithy and everyday medicine in small compass Fourth, the practitioner who has been devoted to some narrow specialty and who requires to keep alert and polished in general medicine Finally, the man who has been parted from formal academic medicine for a little time and who wishes to revise his knowledge therein prior to taking a higher diploma or degree
>
> The book has been written with all these requirements in view Concentration on essentials has been throughout the aim The book should be used to supplement study in the wards and outpatient departments and it should be used to round off and consolidate the work of lecture room, study and bedside. No attempt has been made to go beyond the scope of a practitioner armed with seeing eyes, sharp ears deft fingers open mind and clinical perspective

The book is therefore recommended for purchase by the medical student and practitioner.

Microscopic Slide Precipitation Tests for the Diagnosis and Exclusion of Syphilis. By B S Kline, A.B, M D, Chief of Laboratories, Mount Sinai Hospital of Cleveland Cloth Price $2.50 Pp 99 with 28 illustrations. Baltimore: Williams & Wilkins Company, 1932

In 1926, Kline and Young published a precipitation test for syphilis in which Kahn antigen suspension was mixed with serum on a slide and the results were read by means of the microscope. Since that time, Kline has developed several antigens especially suitable for slide work and has evolved "diagnostic" and "exclusion" tests with heated serum, unheated serum, defibrinated blood and spinal fluid. The diagnostic tests Kline interprets as conservative in sensitiveness but highly specific; the exclusion tests as highly sensitive but not quite specific. In the present manual, the author summarizes and amplifies his published studies. The manual is especially well printed and should be of interest to serologists.

Klinische Elektrokardiographie mit einem Grundriss der Arhythmien. Von Dr. Wilhelm Dressler, Assistent der „Herzstation" in Wien Mit einem Geleitwort von Prof Dr. C. J. Rothberger Second edition Paper Price, 12 marks Pp. 148, with 118 illustrations Vienna Urban & Schwarzenberg, 1932

The aim of the author has been to present the subject of electrocardiography in brief form and from the clinical point of view, so that it might meet the needs of the practitioner This purpose he has successfully accomplished, largely by the omission, or only casual consideration, of theoretical and debatable questions. There is a brief discussion of the principles underlying electrocardiography, the methods employed in taking tracings, the normal electrocardiogram, and alterations due to change of position or increase in size of the heart. Then follow chapters dealing with variations due to unusual origin or conduction of impulses. There is a final chapter on the electrocardiogram in diseases of the heart and vessels. In an appendix there is presented a table that may serve as a guide to one attempting to analyze and interpret cardiac tracings. The book is well written and well printed. The fact that this edition follows the first in about a year speaks for the warm reception of the volume by German-speaking physicians. While it will not displace the excellent works of similar scope that have been written by English, French and American authors, it is a fit companion of these and deserves favorable comment.

Medicolegal

Liability of Interns and Nurses for Negligence

(Nickley v Skemp (Wis), 239 N W 426)

Marvin Nickley bled to death in a hospital, following a tonsillectomy His administrators sued the physician who performed the operation, three interns, who were graduates of medical colleges but not licensed to practice medicine, and two undergraduate nurses, the interns and nurses having been assigned by the hospital to the care of the patient The complaint alleged that the defendant physician who operated performed the operation carelessly and negligently and that all of the defendants "were careless and negligent in the following respects *in caring for said patient In failing and omitting to examine* said child at any time prior to said operation, in omitting to give said child a blood coagulation test at any time prior to said operation and treatment, in failing to properly examine said child throughout the period he was in said hospital, in refusing to call a duly licensed physician to care for said child after said operation, in failing to apply usual and customary methods of stopping bleeding, in failing to properly diagnose and determine the physical condition of said child following said operation, in failing to inform each other of the condition of said patient as observed, in refusing to comply with the demands of the parents of said child that the condition of said child be reported to (Dr ———, the physician who operated) and that said doctor be called, in neglecting to give said child blood transfusions or take other means to revive him, and in permitting said child to bleed to death without proper care, treatment and attention"

All of the defendants except the operating physician demurred to the *complaint on the ground that it failed to state facts* sufficient to constitute a cause of action against them They claimed that the duties that they were charged with having failed to perform were duties which under the law could be performed only by practicing physicians, that the complaint did not charge them with having failed to perform duties which they could lawfully perform, and that their failure to perform duties that they had no legal right to perform could not constitute negligence on their part

The very fact, said the Supreme Court of Wisconsin, on appeal, that the interns and nurses who demurred were in the employ of the hospital in the respective capacities named and were assigned by the hospital to the care of the patient is a sufficient allegation that they owed to the patient the performance of such duties as were ordinarily performed by those occupying similar positions in the hospital The contention of these defendants that the complaint was deficient because it failed to allege specifically each and every duty devolving on them in the course of their care of the patient the court refused to sustain The complaint, said the court, specifically alleges that all of the defendants were negligent in certain stated particulars, and this plainly is tantamount to alleging that the faithful performance of their duties required them to do those things which it is alleged they negligently omitted and failed to do Whether such duties actually did devolve on them or not will be a matter of proof, as will also the determination whether such duties devolved on the interns or on the nurses

It cannot be said that the performance of the duties with which it was alleged the defendants were charged were duties that it would have been unlawful for them to perform The law recognizes that a hospital internship of at least twelve months is required before a license to practice medicine may be granted Although under the law no person may practice medicine, or hold himself out as authorized to practice medicine, without first securing the required license or certificate, yet the law itself requires an internship as a part of one s medical education before one can be licensed to practice This is a legal sanction of the performance of such duties on the part of interns as are usually and ordinarily performed by them The performance of such duties does not constitute the practice of medicine or a representation that the intern is authorized to practice medicine

And so with nurses Most of them acquire their education through hospital service In fact, many hospitals are licensed as nurses' schools by the state board of health The law does not prohibit any one from practicing as a nurse It prohibits any person from practicing or attempting to practice as a registered, trained, certified or graduate nurse, without a certificate of registration Any one who assumes to act as a nurse assumes certain duties, and the failure to perform those duties may constitute negligence

The Supreme Court held, therefore, that the complaint stated a cause of action against all of the defendants, adding that whether they were jointly liable for their several acts of negligence, a question not presented by the demurrer, would more definitely appear from the evidence when the case was tried

Evidence: Testimony by Physicians Concerning Complaints of Patients.—In no decision or text that we have been able to find, says the Supreme Court of Washington, has it been held that a physician called for the purpose of effecting the cure of a patient is not permitted to testify as to his patient's statements concerning past pain and suffering A physician called for the sole purpose of qualifying himself to testify in a trial, and not for the purpose of treatment, may testify, in the state of Washington, as to those statements that were made to him by the person examined, regarding her condition, on which the physician bases his opinion Such testimony is admissible, however, not to prove the condition of the patient at the time of the examination, but only to enable the jury to determine the weight to be given the opinion of the physician The fact that a more restrictive rule as to the admission of such evidence in cases of this character is followed by the United States Supreme Court and by most federal courts was not regarded by the Supreme Court of Washington as a sufficient reason for changing the practice established in the state of Washington According to the appellant in this case, in twenty-seven jurisdictions, including the United States Supreme Court and several other federal courts, the rule runs contrary to Washington practice — *Kraettli v North Coast Transp Co (Wash), 6 P (2d) 609.*

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Issues of periodicals are kept on file for a period of five years only. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending, but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Alabama Medical Association Journal, Montgomery

The President's Message. T. Gaines, Mobile.—p. 445.
Practical Points on Diagnosis and Treatment of So-Called Lymphoblastoma Group of Diseases. A. B. Cannon, New York.—p. 454.
Rôle of Calcium and Phosphorus in Prevention and Cure of Rickets. C. J. Bloom, New Orleans.—p. 467.
Clinical Aspects of Hay Fever and Asthma. G. H. Fonde, Mobile.—p. 471.
The Game Bird as Possible Disseminator of Tularemia. E. Tankersley and I. L. Johnston, Samson.—p. 478.

Bacteriophage.—Walker calls attention to the fact that the nature of bacteriophage is not definitely known, although its properties suggest that that it may be a filtrable virus parasitic on bacteria. Its use does not appear to influence the course of septicemia and genito-urinary infections. Its value in dysentery, cholera and plague has not been definitely ascertained. Bacteriophage is of definite benefit in the treatment of staphylococcus infections so situated that local dressings moistened with bacteriophage can be applied. Among conditions so amenable to treatment are abscesses, furuncles, osteomyelitis, impetigo, and furunculosis of the external auditory canal. In treating such infections, good results are obtained with the use of stock staphylococcus bacteriophage.

An Improved Technic for Perineorraphy.—Gaston performs perineal repair with the patient in the ventral-prone posture. In this position, the field is drained of blood and the thighs are apposed, the latter fact permitting easy apposition of the levator muscles. Regional anesthesia, either extradural or intradural sacral, gives complete relaxation and facilitates differentiation of tissue planes. Very little bleeding obscures the operative field. With the patient in this posture and the pelvis elevated 15 cm. on a pillow, by lowering the plane of the body 15 degrees or more and slightly elevating the thighs above the horizontal, one places the field of operation in a maximal surgical position in the same fashion that a laparotomy wound is exposed. Also, assistants are in a helpful relationship. The method of suture of levator muscles is the other essential improvement in technic. It is an established fact that sutured muscle in these operations tends to break down about the tenth day. The author believes this is due to strangulation by right-angled sutures. He has adopted the plan of placing number 2 doubled chromic catgut sutures through the muscles in line with the muscle fibers. In this way, strangulation will not occur and the needle is never directed toward the rectum. These sutures are interrupted and the number is governed by the degree of tissue separation. With thighs lying close together, the levators fall into apposition without tension. An uncomplicated technic is employed throughout. The mucosa and skin are closed with a running stitch of plain catgut. Redundant vaginal mucosa is not removed but tucked back above the newly made perineal floor. In the case of coexisting hemorrhoids, these are removed by a ligature procedure.

Renal Glycosuria. A. Marble, Boston.—p. 811.
Chronic Essential Pentosuria: Report of Three Cases. A. Marble, Boston.—p. 827.
Therapeutic Effect of Hemolysis, Especially in the Anemias. C. F. Charlton, Pasadena, Calif.—p. 832.
Diaphragmatic Tic Relieved by Section of Phrenic Nerves: Report of Two Cases. H. Smith, Greenville, S. C.—p. 837.
Relation of Sympathetic Nervous System and Generalized Lymphoid Hyperplasia to Pathogenesis of Exophthalmic Goiter and Chronic Lymphatic Leukemia. H. B. Friedgood, Ann Arbor, Mich.—p. 841.
Inefficacy of Spleen Extract in Treatment of Lymphatic Leukemia. J. E. Gonce, W. S. Middleton, H. C. Bradley and M. S. Nichols, Madison, Wis.—p. 850.

Cardiac Manifestation of Hyperthyroidism.—Andrus and McEachern describe experiments which appear to show that the tachycardia of hyperthyroidism and possibly other and more serious phenomena are related to the direct metabolic action of thyroxine or its products on the myocardium. In short, it appears that the cardiac tissue shares in the metabolic upheaval characteristic of this disease. In addition there falls on the myocardium the burden of the increased circulatory demands of the entire organism, the metabolism of which is elevated. These two factors combine to bring to the fore the cardiac manifestations of hyperthyroidism; in individuals whose circulatory reserve has been diminished by age or by organic cardiac disease they may result in myocardial failure. That prolonged hyperthyroidism results in some degree of cardiac hypertrophy seems to be well established. However, hypertrophy does not indicate myocardial damage; much less is it due to the action of a specific myocardial poison. In this instance it is to be attributed to the burden of an increased circulatory minute volume. There is, indeed, little evidence that the heart is permanently damaged. How much functional impairment may be produced by a protracted siege of this disease is a question yet unsettled. The authors conclude that it is, perhaps, the most accurate attitude to look on the heart in hyperthyroidism as suffering from its own accelerated metabolism and from the load thrown on it by the metabolism of the body as a whole. From both of these burdens it can, happily, be relieved by correction of the hyperthyroidism.

Management of the Decompensated Cardiac Invalid.—Hyman and Fenichel summarize the records of 100 decompensated cardiac invalids and note the therapeutic regimen. Eight patients were restored to compensation by physiologic rest and dietotherapy. Mechanical removal of fluid from the serous cavities was practiced in fourteen of the group. Fifty-six patients were specifically benefited by digitalis and all but four in this group had auricular fibrillation. Sixty-four patients, edematous despite physiologic rest, dietotherapy and digitalization, were relieved by the administration of mersalyl with or without the simultaneous administration of urea and the acid salts. Five patients responded by diuresis to urea alone. The authors enumerate thus the four cardinal steps in the management of the decompensated cardiac invalid: (1) physiologic rest and dietotherapy, (2) mechanical evacuation of fluid from the serous cavities, (3) digitalization, and (4) the use of diuretics.

Experimental Chronic Hyperparathyroidism.—White rats, aged from 6 to 12 weeks, were injected daily by Johnson for periods of from ten to forty-three days with parathyroid extract in doses of from 10 to 20 units A Steenbock normal rat diet was given Uninjected litter mates as controls remained well, whereas the injected animals developed, without exception, muscular weakness, hypotonia and skeletal lesions characteristic of osteitis fibrosa osteoplastica (von Recklinghausen), namely, a lacunar resorption of bone with softening and deformity, bending and multiple fracture The cortex and marrow of these bones were largely replaced by fibrous connective tissue containing numerous giant cells and new bone osteoid tissue was also in evidence in numerous cases These experiments support the conclusion that the cause of clinical osteitis fibrosa osteoplastica (von Recklinghausen) is an excess of the parathyroid hormone

Idiosyncrasy to Viosterol—Gordon and Lieberman administered irradiated ergosterol in the form of viosterol (100 D and 250 D) in doses of 1 to 9 drops a day to 200 infants, who were observed over a period of from six months to one year Untoward symptoms were noted in fifteen in the following order of frequency diarrhea, vomiting loss of appetite colic and stationary or loss of weight No case was included in this group unless a definite sequence was obtained consisting of administration of the drug, appearance of ill effects subsidence of the latter on suspension of the drug and finally reappearance on the resumption of viosterol From their study the authors conclude that a definite pharmacologic idiosyncrasy to minute amounts of irradiated ergosterol (viosterol 250 D) exists in some infants According to the incidence found in their series, this is of more frequent occurrence than the literature indicates The drug should be suspended on the appearance of any ill effects and permanently discontinued in the event of reappearance of symptoms on its resumption The idiosyncrasy to viosterol may not be permanent The possibility of an idiosyncrasy should in no way detract from the general use of viosterol in either the prophylactic or the therapeutic treatment of rickets

Scope of Psychotherapy in Schizophrenia P Schilder, New York—p 1181

Auditory Hallucinations in "Nonpsychotic" Children.—Levin presents four case histories of boys who had true auditory hallucinations The boys were "nonpsychotic" in the sense that they showed no acute psychotic disturbances, differing in this respect from the vast majority of the cases already recorded—cases which concern children who develop unmistakably psychotic states with hallucinations, usually at puberty. In all, twenty-four episodes were reported by these boys The episodes are recorded in detail, attention being given to setting, content, and so on Two of the boys showed what probably are early symptoms of a schizophrenic reaction, although at the time of the study the evidence was not conclusive The other two boys, while maladjusted, showed nothing suggestive of schizophrenia or any other psychosis All four boys were below the average in intelligence, two of them conspicuously so The hallucinatory episodes were studied with regard to the quality of the hallucinatory perception, the localization, the presence of accessory sensations, the content and the apparent "functions" that are involved

Pregnancy in the Tuberculous—Jennings and his associates believe that six months after labor is a sufficient time for any harmful effects of pregnancy or labor to appear, and therefore reviewed their full-term group of twenty-seven tuberculous gravidas at that time with observations as follows One died, three became worse, seven remained unchanged, ten improved and four were discharged and are caring for their own homes Two others were delivered less than six months before the study was made, one of whom is improving and the other has shown a slight extension None of the women with minimal tuberculosis were harmed by pregnancy or labor However, the authors are not recommending pregnancy for the tuberculous patient In fact, pregnancy in a tuberculous woman is to be avoided, but when it occurs it must be dealt with, either by interruption of pregnancy or by allowing the woman to go to term They have had gratifying results by carefully treating the tuberculosis while permitting the mother to go to term Out of twenty-seven patients thus treated, only two have died The authors believe that pregnancy should be terminated when complications arise which would call for this procedure in a nontuberculous woman Emphasis is laid on the removal of the baby from the tuberculous mother immediately after birth, for the sake of both

Hematopoietic Test in Pulmonary Tuberculosis—A functional test based on the activity of the hematopoietic system is offered by Curphey and Russell for the study of tuberculous patients They have found that the degree of clinical activity in tuberculosis appears to be in direct relationship to the nature of the hematopoietic response following the intracutaneous injection of either tuberculin or milk The hematopoietic response is in no sense a specific one, so far as the inciting agent is concerned The simplicity of the test and the accuracy of the information obtained recommend it not only as an added means for study of the disease in the hands of those specially trained but also as an aid to those who lack special facilities for the study of the tuberculous patient

Juvenile Tuberculosis Suspects—From the study of a group of children suspected of being tuberculous, Wolff and his associates conclude that in establishing a diagnosis of a tuberculous infection 1 The symptoms and physical signs are not conclusive 2 A history of definite contact is of rather limited value 3 Some roentgenologic observations are pathognomonic 4 The grade of the tuberculin reaction is of definite value in this group It also appears to have a value in deciding the question of the activity of the lesion

Paranasal Sinusitis.—Amano calls attention to the fact that the roentgenographic examination of the nasal sinuses following the administration of iodized oil by the displacement method furnishes additional information as to whether the drainage from the ostia is satisfactory or whether the sinuses or cells are filled with thickened membrane or pus. Negative results after the administration of iodized oil, however, do not always exclude the possibility of disease. The practical value of the opaque displacement method in the diagnosis and treatment fluctuates according to nasal complications, such as hypertrophied turbinates, especially the middle turbinates, and polypi. The removal of these obstructions should be advised before the final roentgenographic examination by the displacement method. The results of the administration of iodized oil by the Proetz method only in his supine position are more accurate in the case of the ethmoid and sphenoid sinuses than in the case of the maxillary and frontal sinuses For the maxillary sinuses, the iodized oil should be injected by puncture through the inferior meatus or by cannula through the natural ostium. The advanced prone or knee-chest position of the displacement method described by the author is recommended, after the Proetz method with the supine position is practiced, in order to give better results in the administration of iodized oil, especially into the frontal sinuses and the anterior ethmoid cells.

Odontoma of Maxillary Sinus.—According to Freedman, a large odontoma of the maxillary antrum is comparatively rare. The majority of odontomas are small, the larger ones usually invade the lower jaw. The diagnosis is not difficult. In a case reported by the author, however, the clinical diagnosis was somewhat obscured by the fact that there was a sinus over the exposed surface of the tumor, suggesting the possibility of malignancy. The treatment is surgical removal intra-orally. The case described was complicated by the presence of a chronic antral suppuration with formation of polypi. The large gaping wound in the maxilla, caused by the removal of the tumor, necessitated two subsequent minor plastic operations to close the fistula leading into the antrum at the outer angle of the wound.

Natural Orifice of Maxillary Sinus.—An attempt was made by Myerson to enter the normal ostium in 170 maxillary sinuses; 138, or 81 per cent, were successfully entered, and 32, or 19 per cent, could not be entered. The Pierce cannula and the author's modification of this instrument were used. It should be remembered that the ostium lies horizontally, obliquely and vertically. In this series 34 were horizontal, 6 oblique and 98 vertical. The proximity of the middle turbinate to the lateral wall does not appear to interfere with the passage of a cannula into the maxillary ostium There may be an occasional exception; in this study there was 1 in 138 instances. The height or prominence of the uncinate and the depth of the infundibulum do not always interfere with the successful passage of the cannula. The angle (bulla-uncinate angle) formed by the posterior upward curve of the bulla and the posterior downward curve of the uncinate is the most constant guide to the location of the ostium On the basis of his observations the author concludes that irrigation of the maxillary sinus through its ostium is a feasible procedure in a sufficiently large percentage of cases to make it worthy of a trial.

Frontal Sinus Operation.—The principal preventable causes of failure of the external operation on the frontal sinuses in a group of cases studied by Anderson were (1) incomplete operation; (2) failure to obliterate completely the sinus cavity in the Killian type of operation; (3) in the Lynch type of operation, the collapse of the soft parts and contracture of the scar closing off the nasofrontal duct; (4) failure to provide adequate room for proper drainage through the nose; (5) failure to maintain the nasofrontal duct long enough after the operation; (6) too early surgical intervention in acute infections, and (7) failure to remove completely all the ethmoid and fronto-ethmoid cells connected with the frontal sinus. The author considers that the selection of the type of operation to be employed in any given case is extremely important and should be suited to the particular problem presented. If there has been considerable destruction of the outer wall of the sinus, changing the contour of the face is not a serious consideration, and the patient must be assured of a relatively high percentage of cures; in such cases the Killian type of operation is employed. If the normal contour of the forehead must be preserved even at a greater risk of not obtaining an entirely satisfactory result, some type of operation which preserves the anterior wall of the frontal sinus should be selected. The bony walls should be preserved sufficiently to prevent collapse of the soft parts, and the nasofrontal duct should be maintained by means of a drainage tube for a long time. The two-stage operation in which the intranasal portion of the operation is done a considerable time prior to the external operation has proved of great value.

Atrophic Cirrhosis.—Moon calls attention to the fact that atrophic cirrhosis is the result of a progressive inflammatory process, proliferative rather than exudative. This process shows variation in activity and may be seen in latent or healed stages. The most active process is seen in juvenile cases. The latent stages are seen most often in adult life The acuteness or latency of the process frequently parallels the clinical manifestations There is evidence, in active cirrhosis, that degeneration and destruction of liver cells precedes the replacement by connective tissue. No morphologic reason is found for placing cirrhosis with fatty changes in a separate class. Cocci may be demonstrated frequently in sections of active cirrhosis. This observation lends support to the supposition that infection is an important etiologic factor.

Multiple Ganglioneuroma.—Haven and Weil report the first case, as far as they can determine, in which ganglioneuromas of benign type were found simultaneously in the cervical and abdominal regions. One of the tumors was located in the region of the stellate ganglion, the others retroperitoneally.

Hürthle Cell Tumor.—According to Eisenberg and Wallerstein, the Hurthle cell, as an integral part of the thyroid, does not exist because it is not always present in the gland, it is identical with the parathyroid oxyphilic cells of Welsh, and it takes its embryologic origin in close relationship with the parathyroid. Hürthle cell tumor of the thyroid is a misnomer because it leads to the erroneous impression that it originates from the tissue of the thyroid. The tumor really originates from parathyroid rests within the thyroid and is an example of parastruma; in its relationship to the thyroid, it corresponds to renal hypernephroma. The symptoms of convulsions and constriction exhibited in a case reported by the authors suggest secretion of the parathyroids.

Intravenous Injection of Epinephrine.—Samson administered epinephrine hydrochloride intravenously to dogs at constant rates over relatively long periods (up to thirteen days). The amounts injected varied from 59 to 246 mg. Consistent tissue changes were found in the liver, kidneys, hypophysis and suprarenals. The pancreas, aorta, spleen, smooth and striated muscle and lungs were found unchanged. The liver showed an intracellular fatty change. In the cases in which the liver was the least affected, small droplets of fat were deposited in the cells surrounding the central vein of the lobule. With more advanced change, the peripheral cells of the lobules contained fat droplets, and the cytoplasm of the central cells was almost entirely replaced by fat. The kidneys showed a fatty change in the cells of Henle's loop and rarely in the cells of the collecting tubules. In the anterior lobe of the hypophysis there was loss of the secretory substance of the chromophobe cells. The alpha cells showed in general a hyperacidophilic staining reaction, appeared to be increased in number and showed a conspicuous distribution in layers around many of the blood spaces. There was a decrease in the number and size of the basophilic cells. In the cortex of the suprarenals, many of the cells showed an altered staining reaction, and there was apparently a decreased endogenous secretion of epinephrine as the result of the injection of epinephrine hydrochloride. The author suggests that the action of epinephrine on certain animal tissues is in part a toxic or a degenerative one.

Avitaminosis. — Thatcher and Sure found metaplastic changes in the posterior part of the tongue, in the salivary glands, and in the respiratory and urinary tracts during early stages of vitamin A deficiency in a large proportion of albino rats that made normal growth, some of which showed incipient ophthalmia or persistence of the cornified stage of estrus as the only sign of vitamin A deficiency, and others of which showed no external signs of A avitaminosis. Bronchitis and pneumonia were also found in several animals that still made slight gains in weight before the termination of the experiment. The authors suggest that metaplasia of epithelial structures in the respiratory tract of man may be the precursor of the common cold, bronchitis and bronchopneumonia resulting from vitamin A deficiency, before any other external symptoms are detected by physical diagnosis.

Experimental Study of Bone Repair.—Dragstedt and Kearns call attention to the fact that the rate of repair of a defect in the dog's femur is reasonably consistent throughout a series of animals if all are healthy and show a good appetite during the experimental period. Dogs that are sickly from distemper, diarrhea or other causes show a definite though not great impairment of the rate of bone repair. This fact should be taken into consideration in all experimental work on growth of bone or repair after injury or fracture. Thyroparathyroidectomy in the dog definitely delays the healing of a bone defect. Healing goes on to completion, however, and is less delayed and approximates the normal if the administration of calcium is such as to maintain the blood calcium level nearly normal. The presence of the parathyroid hormone itself does not seem to be necessary for the process of calcification and ossification. The effect of parathyroid extract on the repair of a bone defect is somewhat complicated. In several dogs observed by the authors the administration of parathyroid extract was followed by the very early appearance of calcium deposition in the callus as judged by roentgenograms, conveying the impression of a facilitated repair. The time of complete healing, however, was not changed. When parathyroid extract was given in reasonably large amounts throughout the experimental period, a definite impairment of healing could be seen. Such dogs, however, frequently exhibited bloody diarrhea and loss of appetite, effects that complicate the interpretation. It does not appear probable that the administration of parathyroid extract will facilitate bone repair in any case except one of parathyroid deficiency. Thyroid deficiency uncomplicated by parathyroid deficiency did not delay the healing of a bone defect.

Epicondylitis Caused by Radiohumeral Bursitis.—According to Carp, an inflammatory involvement of the conjoined tendon at the epicondyle or of a structure in close proximity to it may produce the clinical syndrome known as tennis elbow. One of these structures is the radiohumeral bursa, the anatomy of which is discussed. It is recommended that in all cases of tennis elbow a roentgenogram be made in order to try to visualize an osteitis of the epicondyle or a pathologic and distended radiohumeral bursa. The visualization of the latter condition depends on the character of the fluid contained or of the deposit in the wall. The presence of calcium salts produces a shadow. The author reports eight cases of radiohumeral bursitis in which excellent results were obtained with different types of therapy. Five patients were males and three females. Direct trauma produced the lesion in two cases, indirect trauma in three, combined direct and indirect trauma in two and a questionable trauma in one. Swelling over the bursa was present in five cases, and there were positive roentgenographic findings in five. The operative finding in one case was a calcified radiohumeral bursa. In three other cases the spontaneous absorption of calcium deposits was noted. In the remaining four cases, manipulative rupture of the bursa was the method of treatment used. Radiohumeral bursitis, especially in the presence of swelling, is frequently the cause of tennis elbow. Prompt relief may be expected from rupture of the bursa by firm digital pressure applied over the epicondyle and radiohumeral joint. When this procedure is very painful, a general anesthetic is advisable. Operative therapy is not recommended unless conservative therapy fails to relieve prolonged or recurrent pain and disability.

Diverticulosis of Appendix.—Mulsow believes that diverticula of the appendix are more frequent than the reports in the literature would indicate. He reports nine cases that he observed in the examination of 661 appendixes during the past two years. The presence of a diverticulum in an appendix is of much more importance clinically than it has been considered to be by most writers reporting such cases. It appears that diverticula are more often than is realized the cause of sudden or unexpected perforations in so-called chronic appendicitis or recurring and acute appendicitis.

Dupuytren's Contraction.—Davis and Finesilver state that the disease of the palmar aponeurosis in Dupuytren's contraction is a focal hypertrophy of the connective tissue originating in the walls of the smallest vessels and ending in contraction. While the etiology is obscure, it seems warranted to conclude that the contraction is of idiopathic origin, that it is most apt to occur in middle age and the senile period, and that it shows an hereditary influence. It occurs in all social classes and is much more commonly found in men than in women. There is no single constitutional disease with which it is exclusively associated or of which it is a manifestation. In the majority of cases it does not appear to be specifically caused by trauma or local irritation, though this factor, as well as local or constitutional pathologic conditions, seems at times to have some exciting or contributing influence. In the authors' experience the incidence of Dupuytren's contraction in patients with diabetes mellitus is considerably higher than in the same number of persons, otherwise comparable, without diabetes. The diagnosis is frequently confused by those unfamiliar with the condition with flexion of the fingers due to contraction of the tendons and with congenital contractions. Up to the present time, surgical intervention promises the only permanent cure. This is best accomplished by as complete an excision of the fascia of the palm and its digital fasciculi as is practicable.

Therapeutic Venous Occlusion.—Montgomery describes experiments in which he demonstrated in heparinized animals under sodium barbital anesthesia that after ligation of the superficial femoral artery: 1. Ligation of the concomitant, superficial femoral vein causes no increase in the per minute volume flow of blood through the iliac artery but causes either no change or a slight decrease during the period of examination (from eight to fifteen minutes). 2. Obstruction of the proximal venous return by ligation of the iliac vein, the common iliac vein or the inferior vena cava causes a pronounced decrease in the per minute volume flow of blood, the decrease being more marked the more cephalad the ligature is placed. 3. In confirmation of the observations of Van Kend, Brooks and Martin and others, obstruction of the venous return increases the peripheral arterial and venous blood pressure and, in general, the increase is more marked the higher (more cephalad) the ligature is placed. Because of the marked decrease in the flow of blood which follows obstruction of the venous return proximal to the point of arterial occlusion, and because of the possible danger of producing a serious venous stasis thereafter, it would appear that the use of this principle in the treatment of patients requiring ligation of the main artery of an extremity should be avoided. The employment of ligation of the concomitant vein for occlusions of the injured, but otherwise healthy, popliteal artery is strongly supported by the clinical data. Its use in other locations is still a subject for debate and should await further experimental and clinical studies. The author believes that for the present, in the treatment of acute obstructions of the main arterial supply of an extremity, except the popliteal artery, in the absence of injury to the concomitant vein it seems wise to await the appearance of impending gangrene before resorting to ligation of the vein.

Intravenous Sodium Amytal as Adjunct in Anesthesia.—Ransom calls attention to the fact that sodium amytal administered intravenously is a valuable basal anesthetic for nitrous oxide-oxygen. A better quality of anesthesia and more complete muscular relaxation can be obtained than with nitrous oxide and oxygen unassisted. A considerably higher percentage of oxygen is possible than with gas alone, thus tending to decrease the objectionable cyanosis and making for a greater margin of safety. The easy, quiet induction, along with the slow and gradual awakening, is appreciated by the patient. In nervous patients, or in cases of toxic goiter, the anesthetic can easily be given in the patient's room without exciting suspicion, thus greatly facilitating the "steal" type of operation. Postoperative nausea and vomiting are not greater than with nitrous oxide and oxygen unaided. There is usually an initial fall in blood pressure amounting to 29 mm. of mercury, or 22 per cent, which might be regarded as a contraindication to its use in certain cases; e. g., shock. When used as a basal anesthetic with gas, the incidence of pulmonary complications is not increased.

Abscess of Tongue: Two Case Reports. P. L. Mahoney, Little Rock.—p. 227.

Carcinoma of Cervix Uteri.—Brooksher enumerates thus the contraindications to the use of radium in carcinoma of the cervix uteri: 1. General emaciation and cachexia; in such cases rapid deterioration and death may ensue. 2. A red cell count below 3,000,000 or a hemoglobin of less than 40 per cent; radium may increase the anemia to a dangerous degree. 3. Hydronephrosis or pyonephrosis; the fibrosis produced may increase the obstruction present. 4. Rectovaginal and vesicovaginal fistulas; intense local irritation with sloughing may be produced. 5. Pelvic inflammatory disease; massive necrosis is the likely consequence (this applies also to a foul sloughing condition of the growth itself). 6. Cases in which the whole pelvis is extensively infiltrated with extension from the cervical growth; the end appears to be hastened. 7. Impaired metabolism. A proper dose must cause destructive radiation to reach all cancer cells and at the same time affect the surrounding tissue as little as possible. Usually from 4,000 to 6,000 milligram hours of heavily filtered radium is applied to the cervix and broad ligament regions supplemented with cross-fire roentgen therapy to the pelvis. Saline douches are employed until ulceration is healed, and frequent follow-up examinations should be made to detect possible recurrences.

Physiology of Thyroid.—Cruickshank calls attention to how deeply the thyroid is involved in the control of endocrine function within the human organism, in the regulation of general body growth, and in the proper functioning of the higher nerve centers. The manifold questions which continue to arise with regard to its function are the outcome of its complex interrelation with almost every tissue in the body. The question as to whether the causative factor which produces increased activity of the gland, as seen in hyperthyroidism, is neurogenic or not and is distinct from that which causes the signs and symptoms of thyrotoxicosis remains for further investigation. The physiology of the endocrine glands has altered the outlook on many of the problems which have to be faced both by the scientist and the clinician. It is clear that if one is fully to understand the complex function of, and even attempt to classify, the various types of thyroid disorder with which the clinician is faced, it must be through a correlation and correct interpretation of all the experimental data available.

Cereals in Experimental Anemias.—Summerfeldt and her associates report that rats when placed on an exclusive milk diet after weaning developed a secondary anemia of the nutritional type in from five to eight weeks. In these rats the hemoglobin was reduced from 4 to 6 Gm. per hundred cubic centimeters of blood, instead of the normal value at this age of 13 to 15 Gm. This anemia could be cured when from 33 to 50 per cent of the total diet consisted of a special cereal or a special biscuit in which there was a relatively high proportion of copper and iron. Other foods tested were farina, oatmeal, zwieback, arrowroot and whole wheat biscuits. These did not cure anemia when fed in the same proportions. The authors also investigated the influence of different cereals on the weight of two groups of children. One group was given in the diet ordinary cereals, such as farina, wheatena or oatmeal, while the second group received the same quantity of the special cereal. The groups were kept on the diet for ten weeks, and at the end of this time the diets were reversed for the next ten weeks. The daily intake of cereal was 4 ounces (113 Gm.).

In the case of the special cereal this supplied 27.2 mg. of iron daily, while the ordinary cereals supplied only 1.2 mg. daily. The children on the special cereal made an average gain of 1.2 Gm. of hemoglobin per hundred cubic centimeters of blood, while those on the ordinary cereal made no gain at all.

Blindness from Methyl Alcohol Treated by Lumbar Puncture.—Mathewson and Alexander report a case of methyl alcohol poisoning in which the blindness was successfully treated by lumbar puncture. From a consideration of all the facts they advise that in this condition the following treatment be instituted as soon as possible: (1) repeated gastric lavage during the first four or five days to remove the alcohol excreted by the gastric glands; (2) a large fluid intake to dilute the poisons circulating in the blood stream; (3) pilocarpine sweats and hot packs daily to aid elimination through the skin, and (4) and most important, the withdrawal of as large an amount of cerebrospinal fluid as possible daily, for four or five days. The pressure should not be allowed to fall below 100 mm. of water, to dilute and mitigate the attack of the poisons on the central nervous system, especially the eye. This treatment, of course, is to be used whether the eyesight is damaged or not.

Antibody Response to Pneumococcus Products.—The blood of sixty-three human subjects selected because of the absence of recent infections was studied by Finland and Sutliff for its content of specific antibodies against virulent strains of types I, II and III pneumococci before and after intracutaneous injections of minute amounts of pneumococcus products. The simultaneous injection of the specific polysaccharides of all three types of pneumococci and of proteins and autolysates derived from types I and II pneumococci was followed by the appearance or increase of pneumococcidal power in the whole defibrinated blood and, in most instances, by the appearance of mouse-protective antibodies and agglutinins for one or more types. A single intracutaneous injection of 0.01 mg. of the protein-free type-specific polysaccharide of either type I, type II or type III pneumococci or four similar daily injections was followed, in most of twenty-nine subjects, by the appearance of antibodies against the homologous but not against the heterologous type pneumococci. Poliomyelitis in San Francisco in 1930.—Geiger and Gray call attention to the fact that the outbreak of poliomyelitis in San Francisco and in California as a whole during 1930 was the most extensive yet recorded for these districts. The incidence for San Francisco began to be above the average in June, 1930, and continued in epidemic proportions through the following March; 245 local and 50 nonlocal cases and 32 deaths were recorded during this period. No part of the city was free from the disease, and the prevalence was directly proportional to the density of population. More than 75 per cent of the patients were hospitalized. Males were affected more frequently than females (ratio, 3:2); deaths were evenly divided between the sexes. While a preponderance of the cases occurred in the younger age groups, there were not a few in the older groups, even into the fifth and sixth decades. The fatality rate was higher among adults than in the lower age groups. An attempt was made to determine the types of onset and the symptoms and signs predominant in the early stages of the disease. In the cases that could be classified definitely, the gastro-intestinal type of onset was most frequent, with vomiting or constipation or both as the most prominent signs in the clinical picture. Diarrhea was uncommon. An analysis of the signs tabulated in the central nervous system type of onset would be unsatisfactory because of the lack of definition of the degree of severity and the added factor of varied interpretation by different observers. It may be stated, however, that retraction of the head, indicating meningeal irritation in most instances, occurred with some frequency. Headache, a valuable symptom under certain circumstances, is also difficult of analysis because of the personal equation, but it should be pointed out that, while headache of moderate type was most frequent in the case histories, the severe type was not rare. Fever was present in all but a few cases; the moderate range predominated, although there were numerous instances of relatively high temperatures. Attention has often been directed to the various types and degrees of pain in the early stages of poliomyelitis, causing frequent errors in diagnosis. Pain is usually present, varying from generalized pain comparable to what is seen in true influenza to pain localized in a single muscle group. Pain in the extremities generally preceded paralysis of the part involved and hence is a sign of value in prognosis. The most frequent locations of pain were the neck and back regions, with leg pains and generalized pain next in frequency. A definite interval between the onset of the disease and the onset of paralysis occurred in 154 of the local cases, this interval lying between two and five days in 116 instances (70 per cent). In the nonlocal series the same relative proportion obtains. In the paralytic cases, the many parts and the many combinations of parts paralyzed make detailed classification difficult. Involvement of the extremities, either singly or in combination, was most frequent, occurring in all but twenty-five of the paralyzed cases among the local group and in all but five of the corresponding cases in the other group. The use of convalescent serum appears to have been judicious. Of 167 local patients receiving serum, 109 (65 per cent) were treated on or before the third day, and 140 (83 per cent) on or before the fifth day. It is generally accepted that the serum, to be of benefit, must be administered before the onset of paralysis. Of the 167 local serum-treated patients, 90 (53 per cent) showed definite or apparent improvement, while 30 (18 per cent) showed no improvement. The same relative proportion obtained for a nonlocal group.

Surgery of Hypospadias and Epispadias in Male.—Cecil believes that in attempting to reconstruct deformities of the urethra the urologic surgeon should familiarize himself thoroughly with the principles of plastic surgery. No result can be obtained without an absolute diversion of the urinary stream, and this is not likely to be brought about except by occlusion of the urethra by suture. No drainage tubes, probes or any other foreign bodies should be left in the newly formed urethra. The primary operation for the correction of the deformity of the penis should be done during the first two years of life. It should be complete and no other operation should be done until the deformity is proved to have been cured. Heteroplastic grafts are of no value for the reconstruction of the urethra. There is much experimental and clinical evidence against the use of isoplastic grafts and it is doubtful whether one should attempt to reconstruct a urethra from them. Autoplastic free grafts, such as the use of the appendix or the use of veins, arteries or free skin grafts after the method of Nové-Josserand, are unsatisfactory in reconstructing the urethra, and although urethral canals have been made by the use of this material the results have almost universally been bad. The advancement of the urethra operation of Beck is of use only in minor degrees of hypospadias, in patients who probably should not be operated on at all. In more extreme degrees of hypospadias it is likely to result in failure or in the production of a condition worse than previous to the operation. The Cantas operation of using a pedicle graft of the saphenous vein has not been sufficiently tried to warrant its use. Among other objections to it is that the vein is likely to be too small or is likely to be branched. Small base pedicle grafts, such as are exemplified by the Rochet method, are likely to leave fistula at the base of the pedicle graft. They have a tendency not to join in the development of the penis and to cause retraction of the penis and in some instances contraction of the caliber of the tube. The most successful method of reconstructing the urethra is by the method of Thiersch, which is applicable to all forms of hypospadias. Many cases of epispadias with incontinence are curable. Transplantation of the ureters to the intestine should be reserved for those cases in which one has utterly failed to reconstruct the vesical neck. The best method of reconstructing the bladder neck and urethra is the method proposed by Young.

Primary Epithelioma of Urethra.—According to Kirwin, stricture and chronic urethritis seem to have etiologic significance in the production of primary epithelioma of the urethra. About the only prominent symptom is obstruction of the urinary system or, at times, complete retention. These are common to so many other pathologic conditions arising in the urinary tract as to be of small diagnostic value. Biopsy is the only sure means of differentiation. If this is done early and immediate treatment instituted, the chances of relief are fairly good. Far advanced cases benefit but little from any kind of treatment. The author reports a case in which the original lesion close to the urinary meatus was excised with the bipolar cautery, the metastatic inguinal lymph nodes were removed, and the inguinal wounds treated, first by radon implantation and later by alpine light and high voltage roentgen irradiation. Examination after four months showed slight recurrence, but this was readily controlled by further cauterization. The patient remains in good condition. Complete roentgen examination of the skull, lungs, bones and internal organs was negative for metastasis.

Congenital Solitary Hydronephrotic Infected Kidney.—Moore points out that although unilateral renal agenesia occurs infrequently, it must be considered as a routine in any case in which nephrectomy is contemplated. Invariably, the status of the opposite kidney should be determined before operation. In the conservative treatment of hydronephrosis, many methods have been devised for the purpose of correcting obstructive conditions in the vicinity of the ureteropelvic juncture. The merits of these various procedures must be considered in their application to the individual case at the time of the operation. The factor of renal counterbalance is important in unilateral hydronephrosis; animal experimentation has not revealed positive proof as to whether or not disuse atrophy of the diseased kidney occurs after the other organ has undergone compensatory hypertrophy. The author reports details of a case in which a large infected hydronephrosis caused by a valvular type of obstruction existed, with congenital absence of the opposite kidney. The method of relieving the obstruction is described and the functional and urographic end-results are submitted.

Effects of Pyelographic Mediums on Mucosa.—Because of the constant injury to the bladder mucosa resulting from the use of 25 per cent sodium bromide even when no undue pressure or overdistention is present, and its marked hemolytic action, Mark and Johnson feel that it is not only unsuitable but dangerous as a urographic medium. Sodium iodide in 12.5 per cent solution, though causing a much less degree of hemolysis than sodium bromide, nevertheless produces quite a

In the case of the special cereal this supplied 27.2 mg. of iron daily, while the ordinary cereals supplied only 1.2 mg. daily. The children on the special cereal made an average gain of 1.2 Gm. of hemoglobin per hundred cubic centimeters of blood, while those on the ordinary cereal made no gain at all.

Blindness from Methyl Alcohol Treated by Lumbar Puncture.—Mathewson and Alexander report a case of methyl alcohol poisoning in which the blindness was successfully treated by lumbar puncture. From a consideration of all the facts they advise that in this condition the following treatment be instituted as soon as possible: (1) repeated gastric lavage during the first four or five days to remove the alcohol excreted by the gastric glands, (2) a large fluid intake to dilute the poisons circulating in the blood stream, (3) pilocarpine sweats and hot packs daily to aid elimination through the skin and (4) and most important, the withdrawal of as large an amount of cerebrospinal fluid as possible daily for four or five days. The pressure should not be allowed to fall below 100 mm. of water, to dilute and mitigate the attack of the poisons on the central nervous system especially the eye. This treatment of course, is to be used whether the eyesight is damaged or not.

Antibody Response to Pneumococcus Products.—The blood of sixty-three human subjects selected because of the absence of recent infection was studied by Finland and Sutliff for its content of specific antibodies against virulent strains of types I, II and III pneumococci before and after intracutaneous injections of minute amounts of pneumococcus products. The simultaneous injection of the specific polysaccharides of all three types of pneumococci and of proteins and autolysates derived from types I and II pneumococci was followed by the appearance or increase of pneumococcidal power in the whole defibrinated blood and, in most instances, by the appearance of mouse protective antibodies and agglutinins for one or more types. A single intracutaneous injection of 0.01 mg. of the protein-free type-specific polysaccharide of either type I, type II or type III pneumococci or four similar daily injections was followed, in most of twenty-nine subjects, by the appearance of antibodies against the homologous but not against the heterologous type pneumococci. Some subjects showed a simultaneous lowering of a preexisting pneumococcidal power for heterologous or homologous types. A single intracutaneous injection of 0.1 mg. of pneumococcus protein in thirteen individuals was not followed by the appearance of specific antibodies to any appreciable degree. Single intracutaneous injections of small amounts of autolysates derived from virulent strains of type I, II or III pneumococci were followed in eleven subjects by a more or less general rise in the pneumococcidal power with the appearance of homologous type agglutinins and protective antibodies in about one third of the subjects.

Immunity to Phenomenon of Local Skin Reactivity to Bacterial Filtrates.—Shwartzman describes experiments in which he demonstrated spontaneous active immunity to the phenomenon of local skin reactivity to bacterial filtrates. In one experiment the immunity was nonspecific, while in others it appeared limited to one or two bacterial species. Intradermal vaccination of rabbits with bacterial filtrates induced active immunity to the phenomenon. The specificity of this immunity was tested with graded amounts of toxic factors. The combined intradermal and intravenous immunization in these experiments elicited two types of response, namely, (1) specific immunity, which was obtained in rabbits highly susceptible to the phenomenon (i. e., showing reactions with 1 reacting unit) and (2) nonspecific immunity, which was elicited in rabbits with partial spontaneous immunity (i. e., showing no reactions with 1 reacting unit but susceptible to 15 units one week later). Comparative studies on the reacting potency of "agar washings" and disintegrates (Besredka's method, freezing and thawing method) showed that the first washings of bacterial cells are considerably stronger than subsequent washings and disintegrates. These facts demonstrate once again the extracellular nature of the material necessary for the phenomenon.

Yellow Fever Vaccination.—After preliminary experiments in monkeys, Sawyer and his associates immunized fifteen persons by a single injection of a dried mixture of living yellow fever virus fixed for mice, and human immune serum with separate injections of enough additional serum to make up the amount required for protection. One person was similarly immunized by injecting immune serum and dried virus separately. By titration of the serums of vaccinated persons in mice, it was shown that the immunity rose in a few weeks to a height comparable to that reached after an attack of yellow fever and remained there throughout an observation period of six months. Yellow fever virus could not be recovered from the blood of vaccinated persons or monkeys, except when the latter had received less than the minimal effective amount of immune serum. Neutralization of yellow fever virus by immune serum took place very slowly in vitro at room temperature in the authors' experiments, and could not have been an appreciable factor in vaccination with the serum virus mixtures. A mixture of fixed virus and immune serum retained its immunizing power for eight months when dried in the frozen state and sealed in glass. It appears that the immunizing reaction after yellow fever vaccination was a part of a true infectious process, as was also the observed leukopenia.

In the conservative treatment of hydronephrosis, many methods have been devised for the purpose of correcting obstructive conditions in the vicinity of the ureteropelvic juncture. The merits of these various procedures must be considered in their application to the individual case at the time of the operation. The factor of renal counterbalance is important in unilateral hydronephrosis; animal experimentation has not revealed positive proof as to whether or not disuse atrophy of the diseased kidney occurs after the other organ has undergone compensatory hypertrophy. The author reports details of a case in which a large infected hydronephrosis caused by a valvular type of obstruction existed, with congenital absence of the opposite kidney. The method of relieving the obstruction is described and the functional and urographic end-results are submitted.

Effects of Pyelographic Mediums on Mucosa.—Because of the constant injury to the bladder mucosa resulting from the use of 25 per cent sodium bromide even when no undue pressure or overdistention is present, and its marked hemolytic action, Mark and Johnson feel that it is not only unsuitable but dangerous as a urographic medium. Sodium iodide in 12.5 per cent solution, though causing a much less degree of hemolysis than sodium bromide, nevertheless produces quite a recognizable edema of the mucosa and irritation. Iopax in 30 per cent solution causes approximately the same degree of hemolysis as 12.5 per cent sodium iodide, though its use is unaccompanied by any mucosal or submucosal change, and no evidence of irritation is found. Methiodal in 20 per cent (or normal) solution does not cause hemolysis and is totally free of any irritating qualities. Using either iopax or methiodal, one need no longer have any fear of bilateral pyelograms which are essential in the larger number of cases requiring roentgenographic renal and ureteral study. It becomes quite evident from these experiments that, while there can be no question that overdistention is productive of damage and pain, even in the use of mild solutions, the real factor in causing irritation and mucosal damage lies in the character of the drug itself and its immediate effects on the mucosa

Analysis of Results of Perineal Prostatectomy.—Davis reports that there were nine deaths in a consecutive series of 411 cases of perineal prostatectomy under sacral block anesthesia (2.17 per cent). He states that the chief factors contributing toward maintaining a low mortality rate in prostatectomy are (1) adequate preliminary drainage, (2) the perineal route, (3) detailed attention to hemostasis, and (4) sacral block anesthesia. The chief uncontrolled and unavoidable hazard of prostatectomy today is massive delayed hemorrhage, coming on as late as the end of the second week and occurring in 2 per cent of cases. As determined by questionnaire blanks sent out after intervals of several months following prostatectomy, 82 per cent of these patients voluntarily classified themselves as well, 16 per cent improved, and 2 per cent unimproved. By far the chief reason why these patients tend to classify themselves as improved rather than well is in the persistence of varying degrees of urinary frequency, due to deep-seated and irremediable urinary tract infection. With respect to the matter of selection of cases, out of a total of 200 consecutive patients presenting themselves with varying degrees of prostatic obstruction, 118 were submitted to prostatectomy, 6 were sent home with suprapubic drainage tubes, with the decision pending as to the advisability of prostatectomy, while in 3 instances the patient's condition was considered such as definitely to contraindicate any consideration of prostatectomy. The author believes that the technic of sacral block anesthesia (for prostatectomy) may be made sufficiently exact so that the percentage of failure, formerly considered inevitable, may be entirely eliminated. In a series as yet uninterrupted, he has employed sacral block anesthesia for perineal prostatectomy in 262 consecutive cases without a single anesthesia failure.

Cancer of Colon.—Lahey and Jordan believe that the early diagnosis of carcinoma of the colon must be concluded on roentgen evidence by opaque and air enemas. Any patient with any alteration in colonic function should be investigated by the opaque enema with a question of a colonic new growth. The symptoms of carcinoma of the proximal colon are vague and usually not associated with the signs of obstruction Patients with severe anemia should be investigated for the question of carcinoma of the cecum and ascending colon because of the association of anemia with this lesion. The symptoms of carcinoma of the distal colon are largely those of obstruction and are without severe secondary anemia. Patients with hemorrhoids should be carefully investigated as to the possibility that the underlying cause of the hemorrhoids is an early carcinoma of the rectum. One of the soundest principles of the surgical treatment of carcinomas of the colon is that preliminary enterostomy proximal to the lesion must be employed in all patients with obstruction. Resection of the colon by the Mikulicz plan is applicable to all segments of the colon except the transverse colon, where it can be done but is less satisfactory than at other levels. It is the safest method of removing segments of the colon. The authors describe a method of staggering the implanted loops of bowel on the abdominal wall. By this technic the Mikulicz plan of resection can be applied even to patients with moderate degrees of obstruction, since immediate decompression of the proximal loop can be accomplished as an additional measure.

Familial Achylia Gastrica.—Golob reports the results of a study of familial achylia in a group of two brothers, a sister, and a half-brother born of a different mother. Both the sister and the half-brother died of gastric cancer, the former at the age of 40 and the latter at 31. In both cases the stomach contents revealed all the stigmas of achylia. The other two brothers are living. It is interesting to note that there was another sister in the family who died of diabetes mellitus at 40, and yet another sister, still alive, having the same disease. The cases of achylia illustrate the practical application of preventive therapy; they undoubtedly suggest that cancer respects no age, and the physician relying on a "cancer age" indulges in a false sense of security. The search for the etiology of a true achylia often leads to the diagnosis of a grave malady. It serves both as a danger signal and as a path finder. Achylia is not merely a symptom of a disease but either an anatomic part of a disease complex or a precursor of an oncoming malady. The timely administration of hydrochloric acid may check bacterial activity and prevent the breakdown of the compensatory activities of the auxillary gastric mechanism. It is remarkably effective in gastrogenic diarrhea, pernicious anemia and combined spinal sclerosis, and it is the sine qua non in the therapy of benign achylia. Pernicious anemia must be both preceded and accompanied by achylia, which may be regarded as one of its etiologic factors, through its hemolytic toxin on the hematopoietic organs, and neurotoxin on spinal cord structures. Achylia is a potential forerunner of gastric cancer, laying a fertile soil for malignant implantation through irritation and lowered resistance. Complete anacidity and a short history are strongly indicative of carcinoma; if one adds to it the triad of anorexia, weight loss and progressive asthenia, the diagnosis is certain. Roentgen examination is made only to determine the extent of the region involved. On the other hand, a long history of digestive aberration with even a hyperacidity does not preclude a malignant condition, but if there is the same triad syndrome, a diagnosis of cancer should stand until eliminated. The symptoms of gastric cancer as detected by the conventional mechanical methods of examination are no longer symptoms but complications of the malady. Hence, awaiting the presence of these symptoms must give way to the detection of their approach. The harder it is to recognize gastric carcinoma, the better the prognosis.

Hemophilia in Childhood.—The criteria necessary and sufficient for the diagnosis of hemophilia are formulated by Kugelmass on the basis of experimental and clinical studies. Quantitative determinations of the constituents involved in blood coagulation show the hemophilic deficiency to be in the primary stage of the blood clotting mechanism. Hemophilic blood shows a strikingly low prothrombin content compensated by a correspondingly high antithrombin content. The platelets are normal in number but are physiologically defective, having a slow rate of disintegration. Hemophilic blood is characterized by a blood clotting index which is less than one tenth of the normal. The index constitutes the ratio of the concentration of the substances tending to clot over those tending to favor bleeding. Accordingly, the normal index of clotting function is 0.5 whereas the hemophilic clotting index is less than 0.05. The very low index of blood clotting function is absolutely diagnostic of hemophilia. The index of blood clotting function is increased many fold after transfusion, but the improved clotting lasts for only forty-eight hours. Transfusion does not alter the clotting function of blood in hemophilic persons with joint manifestations. Dietary protein, lipids, vitamins or minerals do not alter the deficient clotting function in hemophilia. Hemophilic persons show the absence of the female sex hormone in their tissues. Ovarian therapy, theelin, and so on produce no change in the hemophilic clotting mechanism. Serum injected and applied locally is not effective in controlling hemorrhage in hemophilia unless it is fresh and rich in thrombin. But nonhemophilic bleeders respond rapidly to any serum and to dietotherapy.

Continuous Irradiation of Entire Body.—Heublein presents theoretical considerations and practical observations which led him to the conclusion that it is desirable to test the value of prolonged continuous irradiation of the entire body in certain types of neoplastic diseases. At the Memorial Hospital in Hartford, an automatic roentgen-ray machine is in use in a special lead-lined ward in which four patients may be simultaneously and continuously irradiated. In addition, provision has been made for the administration to other patients of local intermittent treatments at a target-skin distance of 150 cm., making use of the same roentgen-ray tube. This machine is dependable and economical in operation. The cases selected for the long distance irradiation method were well advanced, and many presented widely disseminated lesions. This choice was made primarily to establish a tolerance dose for the entire body and in the hope of observing some beneficial clinical manifestation, such as a stimulation of some defense mechanism against malignant disease. The maximum dose which the entire body will tolerate has not yet been established. However, investigations to determine this dose are being carried on. At present, the author believes that 25 per cent of a full erythema dose of 750 r measured in air, delivered at the rate of 1.26 r per hour, is a safe dose. Clinical observations and extensive special laboratory tests confirm this opinion. To date, no pronounced beneficial clinical manifestations have become evident, although in some instances encouraging improvement has been noted. It is too early to say whether or not a favorable systemic effect has been, or can be, produced by this method. With intermittent local treatment at 150 cm., definite regressions have been noted in the radiosensitive group of cases. The number of cases in both groups is too small to permit any definite conclusions at this time, although it is believed that the evidence accumulated thus far fully warrants the continuation of the experiment with increasing dosage, within safe limits.

Roentgen Signs of Infantile Scurvy.—Kato believes that the majority of the roentgen signs of infantile scurvy are not pathognomonic. The continued use of such terms as the "Trümmerfeldzone" and "Wimberger's sign" as diagnostic of infantile scurvy leads to confusion. Pelkan's trial in the diagnosis of latent scurvy is a valuable adjunct, but it is not absolutely characteristic. Beading of the ribs is common to infantile scurvy and to rickets. Separation of epiphyses is most frequently found in infantile scurvy, but it may also be found in other conditions. The white line of Fraenkel is the least characteristic of scurvy, for it is merely a phenomenon of hypercalcification at the end of a long bone, which is seen in many diverse pathologic conditions. The one sign which is absolutely unique in infantile scurvy is that of subperiosteal hemorrhage during the third stage of the disease. This can be only inferred clinically on examination of the limbs in the light of a suggestive history, but the final diagnosis must rest on roentgen examination. The author's conclusion is not to be interpreted to mean an attempt to minimize the diagnostic value of roentgenology but rather to emphasize the necessity of broadening the experience of clinicians and roentgenologists in proper evaluation and interpretation of the roentgen signs of infantile scurvy.

Chorio-Epithelioma of Uterus.—Curtis believes that the incidence of chorio-epithelioma of the uterus has been overestimated. Not only is the disease rare but its presence has often escaped clinical diagnosis, so that cases have usually been available for study only after recognition in the pathologic laboratory. A brief report submitted by the author presents a case with a perfect history of chorio-epithelioma in which clinical observation was followed by necropsy and complete pathologic study immediately after death. Incident of this study, colored illustrations were made within the hours immediately following the necropsy, before postmortem discoloration had developed, in order to portray, in lifelike colors, the appearance of the uterine tumors and the visceral metastases. A feature of especial interest was the presence of an easily elicited positive Hegar's sign, which was not only evident during life but was confirmed at necropsy, before the removal of the uterus from the opened abdomen. The fact that Hegar's sign persisted in the presence of living chorionic cells, despite prolonged absence of the fetus, is worthy of note. The appearance of clinical evidence of chorio-epithelioma more than a year and a half after birth of an hydatid mole is also worthy of note. It has been generally assumed that evidence of malignancy may be depended on to appear at a much earlier date. After passage of a typical mole the patient should evidently be kept under close observation for an indefinite period of time.

The Healing of Wounds.—Bird and MacKay describe experiments which show that moderate dehydration in rats, comparable to states of dehydration observed clinically, result in striking weakness in gastric wounds and in the gastric walls elsewhere than at the wounds. These effects are marked up to at least fourteen days after operation, the limit of time to which the experiments were carried. It is suggested that dehydration has a marked inhibitory effect on the processes of repair in general and that even after as short a period as four days there is sufficient destruction of body protoplasm to weaken considerably many tissues, whether or not they have been operated on. Such experimental results demand a continued and reiterated emphasis on the value of an adequate supply of fluid for injured patients of all types. It is, of course, important to bear in mind that dehydration can neither be prevented nor cured by water alone. Sodium chloride must be applied in addition.

Spinal Anesthesia.—On the basis of experimental work on dogs, Bower and his associates conclude that the fall in blood pressure following the injection of an anesthetic into the subarachnoid space is not due to a collection of blood in the splanchnic area. When the anesthetic ascends to the fourth thoracic nerve roots or higher in the dog there is an associated dilatation of the heart. The marked fall in blood pressure is mainly cardiac. Paralysis of the intercostal and phrenic nerves interferes with normal chest expansion and diaphragmatic excursion, causing a damming back of venous blood in the right heart and its tributaries. When the ascent of the anesthetic in the spinal canal is gradual, the blood pressure drops gradually and reaches its minimum in from fifteen to twenty minutes. When the anesthetic ascends rapidly and sufficiently high to affect not only the nerves of respiration but also the respiratory and vasomotor centers, the fall in arterial pressure is almost immediate but may be preceded by an asphyxial rise. Sudden deaths following intraspinal injections may be cardiac, cardiac and respiratory, or respiratory. Epinephrine and ephedrine did not prevent cardiac dilatation in the authors' experiments. The Drinker respirator alone will resuscitate an animal that has received the full adult dose of a spinal anesthetic into the cisterna. Up to the present time there is no known method of absolutely preventing deaths from spinal anesthesia, but artificial respiration offers the best means for combating respiratory embarrassment and the fall in arterial pressure.

Postoperative Thrombosis, Thrombophlebitis and Embolism.—Bancroft and Stanley-Brown believe that loose abdominal dressings, early postoperative feeding, and administration of fluid relieve postoperative distention and distress and may diminish thrombosis. Blood studies show that certain individuals are more prone to develop thrombosis than others. The blood abnormalities can frequently be improved by diet and intravenous medication. There are probably substances liberated in the blood through the effects of operative and postoperative trauma and infection that tend to change normal into abnormal clotting factors. The elimination of operative and postoperative trauma should diminish this incidence. Routine blood studies frequently show alterations in the clotting factors before the onset of thrombosis and thrombophlebitis. It is the authors' belief that in a number of cases thrombosis and embolism may be aborted by administering a diet low in fats and proteins and the intravenous administration of sodium thiosulphate.

Syndromes of Gastro-Ileostomy and Gastro-Ileac Ulcer.—Rivers and Wilbur call attention to the fact that the general characteristics of secondary peptic lesions which occasionally occur about a gastrojejunal stoma can be reduplicated even to certain minute histopathologic characteristics by similar lesions which may develop subsequent to the formation of anastomosis between the stomach or the jejunum and the lower part of the ileum. Clinical evidence is suggestive that the potentiality for the development of peptic lesions arises whenever and wherever any segment of intestinal mucosa is exposed to the eroding action of the gastric chyme. It would appear that a syndrome fairly characteristic for gastro-ileostomy can be formulated. If, following an operation performed for a gastric lesion, particularly if there is some evidence that a side-tracking operation had been attempted, the patient begins to lose weight, to have lienteric diarrhea, fecal vomiting, and fecal belching, and to lose weight rapidly despite normal appetite and normal ingestion of food, the suspicion should arise that an anastomosis has been made erroneously between the stomach and the ileum or colon. Similar symptoms may be produced by anastomosis between the jejunum and the ileum or colon. If, following a period during which such symptoms have developed, pain is superimposed, and if this pain is situated lower than the original pain and arises from thirty minutes to several hours after meals, if it is referred downward or through to the back and is to any degree amenable to the ingestion of food or to the taking of an alkali, the presence of a gastro-ileac ulcer may well be suspected. The surgical formation of gastro-ileostomy in itself may not be productive of definite symptoms, because in certain cases the pylorus remains patent and maintains its physiologic function so that most of the food reaches the duodenum and the small intestine in the normal fashion, thus preventing emaciation, dehydration, and lienteric stools. The more the gastric contents leave the organ through the stoma, the more definite the syndrome of gastro-ileostomy will become.

Treatment of Forme Fruste Peptic Ulcer.—The plan of treatment used by Singer and Vaughan for forme fruste perforations in gastric ulcer is as follows: Practically all patients seen within the first twenty-four hours of onset are operated on, since in the early stage it is difficult or impossible to determine whether or not the rupture is firmly closed and leakage has ceased. When the patient is seen for the first time during the second twenty-four hours and it can be determined with a reasonable degree of certainty that the perforation is securely sealed and the peritonitis is limited and receding, the authors are inclined to refrain from surgical intervention. If there is any doubt as to the closure of the perforation, immediate operation is employed. If the patient is first seen after the second postoperative day, it is generally a simple matter to decide whether or not spontaneous closure with only insignificant leakage has occurred. A peritonitis which is still diffuse and active at this time indicates that the perforation is not the forme fruste type. In the nonsurgical treatment of the late forme fruste ruptures, the stomach when distended with fluid is aspirated by siphonage, the patient is required to lie continuously on the left side, and food and fluids by mouth are withheld for from three to four days or even longer. Fluids are furnished by proctoclysis and hypodermoclysis. The authors wish to sound a note of warning against the indiscriminate application of these principles of treatment. The recommendations submitted by them apply exclusively to forme fruste perforations. The presence of only slight or moderate improvement during the first twenty-four hours does not constitute proof of a forme fruste rupture or indicate that leakage has been completely checked. Unless the recovery from the peritonitis is almost complete, a forme fruste perforation cannot be assumed. If one cannot be reasonably certain of the type of perforation present, the patient is best treated according to accepted current teaching.

Transplantation of Tendons with Stabilization of Paralytic Talipes.—According to Williamson, final operative treament in infantile paralysis should not be undertaken until the residual stage at least two years after the onset of the disease has been reached. In untreated cases, deformities should be corrected and a period of conservative treatment by physical therapy and mechanical fixation instituted before any operative treatment is undertaken. Transplantation of tendons, although attractive from a theoretical standpoint, has not proved satisfactory in itself. As stability of the feet with freedom from painful lateral deformities is the most desirable end-result, an operation designed to fuse joints through which the deformities occur should be performed. Any lateral muscles having useful power must be transplanted into the achilles tendon or front of the foot as indicated. Children should be at least 6 years and preferably over 10 years of age before any bony operation is done. A brief consideration of the rules governing the transplantation of tendons is offered together with a brief description of subtalar arthrodesis. A change in the nomenclature of operative procedures to that taught at present in the medical schools is suggested. Six cases are briefly reported.

Treatment of Obstructive Lesions of Biliary Tract.—Walters directs attention to the effects of cholecystitis on the liver, on the common and hepatic ducts, and on the pancreas, and to the beneficial effects of cholecystectomy, with prolonged drainage of the common bile duct, as was noted in a group of patients who were jaundiced at the time of operation, but in whose common or hepatic ducts there were no stones. It is pointed out that penetrating ulcers of the posterior duodenal wall perforating into the pancreas produce a group of symptoms that simulate biliary obstruction. Frequently these ulcers pass unrecognized because of the normal appearance of the anterior duodenal wall. Other significant matters of which account is taken are an abnormally prolonged coagulation time of the blood, a change in the color, consistence and conformation of the liver, and a change in the color, quantity and quality of bile that drains out. These seem to be indexes of hepatic function.

Ureter After Nephrectomy.—Scholl believes that in the majority of cases, even when the ureter is extremely dilated, it is not necessary to remove the ureter when doing a nephrectomy. In cases in which the ureter and any retained contents are infected and obstruction to the lower ureter occurs, this obstruction must be relieved. If it is impossible to relieve this obstruction by conservative methods, a primary nephro-ureterectomy or a secondary ureterectomy should be performed.

Surgery of Undescended Testes.—According to Hepler, the functional imperfection of the undescended testis is the result of degeneration of the germinal epithelium from thermic changes because of the lack of scrotal protection. Because these changes do not take place before puberty, when there is an attempt to elaborate a mature germinal epithelium, placing the testis in the scrotum before this period will conserve its function and permit it to develop normally. The essential features of a successful orchiopexy are a careful and complete separation of the component structures of the spermatic cord without interference with the blood supply of the testis, and the temporary fixation of the testis to some structure outside the scrotum to guard against retraction until this inevitable tendency has been overcome. The importance of this temporary scrotal and testicular fixation cannot be overemphasized. The author describes a modification of the Torek operation which has given satisfactory results in twelve cases in the last year.

Vasovagal Syncope and Carotid Sinus Mechanism.—Lewis states that thirteen years ago he became interested in what may be called common fainting attacks, or, more precisely, vasovagal syncope. Although he described his type of syncope in young soldiers in ill health, he recognized then, and has recognized since, that its incidence is wide. It is, in fact, the commonest form of syncope or fainting. It occurs in both sexes; it affects the young especially but by no means exclusively. There are states of the body that can be named as predisposing to it. Thus it is more usual in people who are out of condition or actually in poor health; it is more frequent after an illness or chronic infection. The presence of fatigue, a period of fasting, confinement to an overheated, overcrowded room, are not unusual attendant circumstances. The central feature of the attack is the syncope. In some cases the loss of consciousness occurs without warning of any kind and may then result in a heavy fall and injury. More usually the subject is aware that fainting is imminent and sits or lies down deliberately, or slips, or falls more slowly and involuntarily to the ground. The warning consists of a feeling of instability or uncertainty, a dimming of vision, and a feeling of giddiness. There is never any sense of rotation or of objects swinging around before the eyes, often a valuable point in differentiating auditory vertigo. The attack occurs rarely, if ever, while the subject is lying down, a point that in the history is often crucial in differentiating the attack from major attacks of cardiac syncope or epilepsy. From the start there is a progressive lowering of blood pressure and almost always a steep fall of heart rate, the pulse usually becoming imperceptible and the heart rate falling to 50 or 40 (unusually to 30 or 20) beats a minute. Pallor accompanies this fall of blood pressure; increasing in intensity, it ultimately becomes extreme in the face but is absent or much less evident in dependent parts, such as the hands. This pallor is of the type associated with simple drainage of blood from the skin to dilating visceral vessels. The cerebral manifestations indicate the degree and duration of cerebral anemia and, from the standpoint of the circulation, are to be regarded as incidental. When the circulatory changes happen gradually, syncope is led up to by feelings of insecurity and dimness of vision, and objectively by incoordination, confusion of speech, restlessness, yawning, and decreasing response to questions and to physical stimuli; actual loss of consciousness with flaccidity is the rule. If the changes are sufficiently profound, the pupils dilate and the conjunctival reflex vanishes; there may be slight clonic movements of the face, upper limb, and trunk. The tongue is not bitten, nor is the urine passed. In the severer attack, respirations are slow, deep and sighing; sweating is almost invariable, breaking out on lips and forehead, or over the body generally; usually free, it sometimes drenches the clothing. The author also calls attention to the fact that in recent years much interest has been aroused in a mechanism connected with what is now called the sinus caroticus. This mechanism has been shown to exercise a powerful controlling influence on heart rate, blood pressure and respiration, and especially in regulating the circulation to the brain. A rise of pressure within the carotid sinus results in a reflex lowering of heart rate and of systemic pressure; the former is produced through the vagus, and the latter through vasomotor nervous channels and through an effect on suprarenal secretion. The carotid artery contains the receptor part of the mechanism, the glossopharyngeal nerve conveys the impulse to the medulla; here the impulses exert two chief influences—they inhibit the heart and they depress vasomotor tone. This remarkable and seemingly purposive grouping of reflex cardiovascular effects also occurs when the depressor nerve is stimulated; it must surely depend, therefore, on a close linkage of the efferent channels by central parts of the nervous mechanism. And, given this linkage, it is highly probable that the central and efferent parts of this mechanism are disturbed in the clinical syndrome of vasovagal syncope, in which strong vagal effects are likewise combined with depressor vasomotor effects.

Effect of Solution of Pituitary in Malignant Disease.—Riches and Kremer report the results they obtained in the treatment of nine persons with malignant tumors by means of injections of solution of pituitary. Except in one case, in which there was a local diminution in the edema of the tongue overlying the growth, there was no beneficial effect that could be attributed to the injections. All the cases followed the usual course of the disease for the particular type of growth. In no case was life prolonged, nor was there regression of any of the growths.

Septic Foci and Normal Labor.—In an analysis of the records at the Oxford Maternity Home for the five years 1926 to 1930, Leyton found that the average length of normal labors in that institution has increased. The number of normal women living in the town of Oxford who had long labors (primiparas over twelve hours and multiparas over six hours) increased from 19.26 per cent in 1926 to 45.25 per cent in 1930. Among the women living in the country districts around Oxford it rose from 6 per cent in 1926 to 13 per cent in 1927, 19.5 per cent in 1928, 52.75 per cent in 1929, and 47.73 per cent in 1930. The only common factor found in cases of long labor was evidence of a chronic septic focus. A study of the temperature charts of patients in whom a chronic septic focus had been noted at the antenatal clinic revealed the fact that their temperature usually rose to 99 F. on three or more occasions during the puerperium (usually ten days). An analysis of the notes of the other normal cases which showed a rise of temperature on three or more occasions during the puerperium showed that these almost invariably were long labor cases, and, conversely, that short labors had an even temperature during the puerperium. Comparatively short labors are appearing in the recent records more rarely, and the actual average length of time spent in labor has increased by two hours in the last five years.

Chronic Ulcers of Leg.—From many years' experience in general practice, confirmed by recent clinical and bacteriologic tests, Umanski has come to the conclusion that even the most extensive ulcers of the leg of nonspecific character may heal under adequate ambulatory local treatment, provided the patient's general health is not too greatly impaired. The treatment should be directed toward eliminating microbic infection and stimulating the inherent natural forces of repair of the damaged tissues. A solution of 8 to 12 per cent of balsam of peru in glycerin and alcohol answers this purpose best, since not only has it a bactericidal action on the pyogenic organisms of the ulcer but it simultaneously promotes repair of damaged tissues by stimulating the granulating as well as the epithelization process. Glycerin acts as a good excipient for the balsam of peru and is useful as an exosmotic and hypertonic for draining ulcers and intensifying the antiseptic and penetrative action of the balsam of peru. Other methods should not be used until the method described has been given a fair trial. In ulcers of distinctly varicose character, some support of the limb by elastic bandages may be applied for some time, preferably only during the daytime.

Serum Proteins in Leprosy.—Rao presents the results of a study of the serum proteins in 252 cases of leprosy, with especial reference to hydnocarpus treatment and in fifty-six healthy controls. Serum albumin shows a significant reduction in lepers as compared with healthy controls and this reduction is probably caused by leprosy per se. Lepers of all types, except certain phases, have a considerably higher globulin value than the healthy controls and the untreated leper controls. The effects of an injection of any hydnocarpus preparation seems to be a marked increase in the globulin value in all types of cases detectable on the second day after the injection. The further changes in the serum globulin on other days after the injection are described. A certain difference in the behavior of the globulin value in the two main types of lepers, namely, cutaneous and neural, was noted. The formaldehyde test in uncomplicated cases of leprosy is never positive. There seems to be no definite relationship between solution of formaldehyde coagulation and serum globulin in lepers or lepra reactions.

Electric Charge of Erythrocytes.—According to Chopra and Chaudhury, the negative electric charge of erythrocytes in isotonic solution of dextrose is more susceptible to changes in ionic environment than in physiologic solution of sodium chloride. The higher the alkalinity of the environment, the greater is the negative charge. The greater diminution in the negative charge on the alkaline side of the medium in presence of a definite concentration of quinine dihydrochloride shows a relatively higher absorption of basic alkaloidal ions. These facts suggest that the higher activity of quinine salts in an alkaline solution is at least partly due to the relatively higher absorption of the alkaloidal ions in such a medium.

Protection with Antivaccinal Serum Against Viruses of Vaccinia and Variola.—The protective action of antivaccinial serum obtained from hyperimmunized buffaloes was studied by Pandit and his associates in experimental infection of monkeys with the viruses of vaccinia and variola. The viruses were introduced by scarification and the serums were given subcutaneously in all cases. When the serum was administered along with the virus, a considerable degree of protection was obtained against the viruses both of vaccinia and of variola. When the serum was given at varying intervals, after vaccination with vaccine lymph, no absolute protection was demonstrated in any case but the course of vaccination was modified to a slight extent. On the other hand, the serum gave considerable protection against variola virus even though it was administered four hours after the virus was introduced by scarification. Even if the serum was given twenty-four hours after, the course of the reaction was considerably modified. Serum obtained from convalescent cases of smallpox showed a much higher degree of protection than did that obtained with the buffalo immune serum. The results warrant an extension of efforts both to produce from animals an antivaccinial serum of high potency and to investigate the benefit that may be obtained by the use of convalescent human serum.

Cancer of Rectum.—Cancers of the rectum are divided by Dukes into A, B and C cases according to the extent of spread. A cases are those in which the growth is limited to the wall of the rectum; B cases those in which there is extrarectal spread but no lymphatic metastases; C cases those in which metastases are present in the regional lymph nodes. A striking difference is found in the operative mortality rate and in the survival period after operation in these three groups. There is reason to believe that in A cases the disease is completely eradicated by rectal excision, and the excellent results of operative treatment confirm the opinion that lymphatic metastases are not found until a rectal carcinoma has spread by direct continuity to the extrarectal tissues A good prognosis is justified also in B cases, though slightly less favorable than in A The results of surgical treatment in C cases are disappointing

Melanotic Tumor of Ganglion Cells—Millar describes a case of a highly malignant tumor composed of cells of nervous origin whose structure approximated, in a greater or lesser degree, that of ganglion cells The more highly differentiated ganglion cells were loaded with pigment this was a true melanin and was present in sufficient quantity to make parts of the tumor as black as an ordinary cutaneous melanoma The author adduces evidence to show that the tumor arose from nerve cells in the seventh left thoracic sympathetic ganglion In view of the undoubted nervous origin of this tumor, he believes that it is both possible and likely that a similar origin can be postulated for some at least of the melanomas arising in the suprarenal medulla

Motile Organisms from Nonmotile Cultures—Colquhoun and Kirkpatrick call attention to the fact that when grown on semisolid medium, e g, one containing 0 3 per cent agar plus 5 per cent gelatin, many organisms develop motility which are nonmotile when grown in the ordinary fluid or solid mediums Motile strains have been recovered in this way from nonmotile cultures of Bacillus typhosus Bacillus proteus, the Salmonella group and Bacillus pestis, Bacillus mallei and Brucella melitensis In certain cases the original nonmotile cultures when stained for flagella showed the presence in abundance on such structures, e g, Bacillus typhosus from the feces of a chronic carrier In others, e g, Bacillus suipestifer, flagella were extremely scanty, only a few bacilli showing a single flagellum In others, again no flagella could be demonstrated Certain nonmotile strains of Bacillus typhosus, Bacillus pestis, Bacillus dysenteriae Shiga and Bacillus dysenteriae Flexner-Y failed to develop flagella and motility after repeated subculturing in semisolid mediums A satisfactory explanation of the phenomenon described has not been obtained But the evidence suggests that the development of flagella and motility depends on a suitable viscosity of the medium in which the organisms are growing

*Injection of Umbilical Vein in Retained Placenta D W Currie—p 1087
*Serum Agglutinations to Typhoid Group in Cases of Pulmonary Tuberculosis J R A Madgwick and F Partner—p 1091

Control of Carbohydrate Metabolism—Macleod states that from the evidence at present available it may be justifiable to postulate that when the requirements are more or less steady, the rate of sugar production is regulated by alterations in the balance between insulin and epinephrine in the blood, but that when there is a sudden call for sugar to meet the demands of great muscular activity, direct nervous stimulation of sugar secretion by the liver is set up As to how the balance between insulin and epinephrine is adjusted, it is possible, since the secretion of each of these hormones is subject to nerve control, that the sugar concentration of the blood supplying the nerve centers is the stimulus that acts on them In the light of the experiments which the author describes, these centers are probably situated somewhere in the pons, and the discharge of impulses from them, which is set up by decerebration, acts in such a way as to cause increase in the secretion of epinephrine and decrease in that of insulin, at the same time that dextrose secretory impulses are discharged to the liver

Injection of Umbilical Vein in Retained Placenta—Currie summarizes the procedure adopted in the Leeds Maternity Hospital for the conduct of the third stage of labor Immediately after the delivery of the child, the patient is turned on her back and the cord is placed in a sterile dish between her thighs The height of the fundus is noted, but the uterus is not touched unless undue loss of blood necessitates the use of gentle massage to induce a contraction In most cases the patient is left undisturbed for twenty minutes, except that the height of the fundus is observed from time to time, also the presence of hemorrhage In normal cases the simple tests for the position of the placenta are made (lengthening or shortening of the cord, the height of the fundus, and the shape, contour and mobility of the body of the uterus) If such tests reveal that the placenta is lying in the lower segment or vaginal vault, the fundus is massaged to elicit a contraction and the uterus is then used as a piston to push the placenta out of the vagina If the tests show that the placenta has not left the uterus, they are repeated at intervals of five minutes No alarm need be felt if the placenta is retained without hemorrhage, but should the placenta be retained and a postpartum hemorrhage occur this will continue until the placenta is removed It was formerly the custom at the Leeds Maternity Hospital to attempt to express the placenta by means of Credé s maneuver, and should this be unsuccessful to repeat the maneuver at intervals and under an anesthetic if necessary before resorting to the dangerous manipulation of manual removal Now injection of the umbilical vein is practiced A Scannel blood transfusion apparatus is used This consists of a 20 cc syringe with a three-way tap and thus overcomes the delay made necessary by the repeated disconnection of the ordinary record syringe The patient is placed comfortably in bed with the lower part of the abdomen and thighs exposed, the thighs at the same time being abducted The vulva and the surrounding skin and the cord are thoroughly cleansed and the cord is placed on a sterile towel lying between the patient's legs The needle is inserted into the umbilical vein about 6 inches (15 cm) from the vulva, and held in position by a ligature It is better to leave some undamaged cord between the needle and the vulva in case it is necessary to reinsert the needle The injection of physiologic solution of sodium chloride is now commenced, and this is injected at the rate of from 300 to 400 cc in two and a half minutes, 350 cc is about the average amount of fluid used On completion of the injection, artery forceps are placed on the cord, the needle is removed, and the placenta is expressed if it has not been already spontaneously delivered As the fluid enters the placenta the fundus of the uterus is felt to rise up in the abdomen and later strong uterine contractions occur The author does not deem it necessary to await the spontaneous expulsion of the placenta but rather aids its delivery by immediate expression, during a contraction, after the completion of the injection The method presents to the physician, whether of a clinic or in general practice, an easy means of obtaining completion of the third stage of labor, without the aid of any further instruments than he normally carries in his bag, without the necessity of much preparation or anesthetic, with a fair proportion of success, and above all without the great fear of puerperal infection and risk of death that accompany the manipulation now generally practiced, namely, "manual removal"

Serum Agglutinations to Typhoid Group of Organisms—Seventy-three cases of pulmonary tuberculosis with a negative history of TAB inoculation or infection were examined by Madgwick and Partner for agglutinins to the typhoid group of organisms and these were found to be present in the blood of twenty-five, or 34 2 per cent These twenty-five cases showed reactions of diagnostic significance, which persisted for three months during the course of the investigation Control investigations of 100 cases of nontuberculous mental hospital patients showed slightly positive reactions in five cases only, one of which was possibly the result of prophylactic inoculation against the typhoid group of fevers during army service The results suggest that, in a case showing persistent agglutination reactions of average low titer and not showing the rise of titer associated with the progress of true typhoid infections, the possibility of tuberculosis should not be overlooked

*Scintillating Scotoma in Diagnosis of Pulmonary Tuberculosis P Braunstein and J Stephani —p 140

Scintillating Scotoma in Diagnosis of Pulmonary Tuberculosis.—Braunstein and Stephani noted scintillating scotoma in 80 per cent of patients with pulmonary tuberculosis examined in an investigation covering several hundred cases This type of scotoma manifests itself clinically in the form of an attack which starts with the appearance of a dark spot in front of both eyes The spot extends accompanied by a vibratory motion, called scintillations, at its periphery and zigzag colored lines until there is a considerable visual defect, frequently of hemianopic form Sometimes it is even accompanied by headache, malaise, vertigo, nausea and vomiting The attack, which lasts from several minutes to a quarter of an hour, resists all treatment and finally ceases completely While it cannot be considered a pathognomonic sign the authors think it should be placed among the list of classic general symptoms of pulmonary tuberculosis whether it occurs during the premonitory period or the early or the advanced stage of the disease They think that it not only is a reliable sign of pulmonary tuberculosis but also has a certain prognostic value, as its presence and persistence during the course of the disease indicates, better than many other tests, a weakened resistance

Presse Médicale, Paris

40: 925 940 (June 11) 1932

*Treatment of Alimentary Anaphylaxis by Liquid Petrolatum C Richet and R Couder —p 925
Pathogenic Agent of Typhus Fever J Segal —p 926

Treatment of Alimentary Anaphylaxis by Liquid Petrolatum—Richet and Couder, on the basis of clinical experience, state that liquid petrolatum given in doses of one teaspoonful at the beginning and at the middle or end of each meal is capable of preventing anaphylactic disturbances in case of alimentary anaphylaxis They report five cases three of urticaria, of many months' duration, one of diarrhea of twenty years' standing and one of intense vertigo and abdominal pain of six months' duration in which the treatment with liquid petrolatum was effective within a few days This method may be associated with other forms of antianaphylactic therapy, such as peptone therapy or elimination diet In two cases the cure continued after the treatment was stopped The authors thought at first that the oil acted as a semiprotective coating for the digestive mucosa which retarded the absorption of the anaphylactizing proteins, so that the organism had time at each meal to antianaphylactize itself However, numerous experiments on guinea-pigs contradicted this explanation, so the mechanism of this therapy still remains obscure

*Prophylaxis of Postoperative Venous Thrombosis H Iselin —p 553
Functional Process in Nervous System F Verzar —p 556
Therapeutic Use of Organic Gold Salts K Ziegler —p 560

Prophylaxis of Postoperative Venous Thrombosis.—Iselin stresses the following rules as essential for the prevention of postoperative thrombosis 1 Injury of the vascular epithelium should be avoided before, during and after operations Endothelial injuries may result from intravenous administration of chemical substances and consequently these should be avoided 2 The physiologic composition of the blood should be respected and consequently the intravenous injection of large amounts of sodium chloride solutions is inadvisable To administer fluid to the blood the author considers the subcutaneous administration as better and he emphasizes the significance of isotonia 3 In order to improve and accelerate the circulation, he recommends the application of remedies that effect hyperemization, such as warm mustard applications to the legs These not only counteract stasis in the legs but also aid in drawing the blood away from the overfilled portal system after laparotomies, and from the lungs following inhalation anesthesia They should be applied soon after the operation, in order to be effective during the postoperative circulatory crisis, which develops particularly in obese patients

Archivio Italiano di Urologia, Bologna

*Strictures and Congenital Atresia of Urethra G Tarozzi and G Bucciardi —p 539
Study of Diuretic Cerebral Hormones by Puncture of Saline Center in Floor of Fourth Ventricle E. Mingazzini —p 601

Strictures and Congenital Atresia of Urethra.—Tarozzi and Bucciardi state that in complete congenital closure of the urethra there is also congenital dilatation of the bladder, whereas in stricture there is in addition to this dilatation a compensatory hypertrophy of the bladder wall Two types of tumor come into question in urethral stricture, namely, fibromyoma of the bladder and the ganglioneuroma found in certain zones of nervous ganglial elements Neoformations derived from blastomatous proliferation of nervous elements consist of neuroblastoma, paragangliomas and ganglioneuromas In a number of the authors' cases, the stricture consisted of a hypertrophic and hyperplastic process involving all the muscular, connective tissue and nervous layers of the bladder and was accompanied by hypoplasia of the genital organs In a few cases the presence of hyperplastic nervous tissue in the bladder militates against the fibromatous and fibromyomatous character of the bladder changes When there is no closure but simply congenital stricture of the urethra, the resulting alterations through dilatation and hypertrophy of the bladder are already established during intra-uterine life and are more accentuated after birth Congenital urethral strictures are either partial (valvular) or annular Nothing is known of the causes and primary conditions by which a congenital stricture is determined It occurs generally in males Some hold that only those cases are congenital wherein the form of the utricle and the disposition of the glands of the verumontanum determine a true hyperplasia of the urethral crest, with production of a partial stricture corresponding to the internal urethral orifice Others maintain that toxic and infectious processes in intra-uterine life, resulting in deformity and sclerosis, can easily determine stricture

Technic of Examination of Motor Function of Urinary Bladder E Ragnotti —p 545
*Importance of Renal Function in Postoperative Insufficiency of Liver L Stropeni —p 554

Gallstone of Rare Composition—Uffreduzzi found in a patient a gallstone consisting almost completely of calcium carbonate On reviewing the case literature of gallstones he did not find anything similar to his case He states that calcium frequently enters into the composition of biliary stones but only in combination with bilirubin or cholesterol or in compound stones The mucosa of the cholecystic wall undoubtedly produces calcium but this cannot explain a pure calcium carbonate calculus

Renal Function in Postoperative Insufficiency of Liver.—Stropeni states that insufficiency of the liver is objectively manifested above all by the appearance of ketone bodies in the urine (acetone, diacetic acid, beta-oxybutyric acid) He studied both the acetone content of the urine and the amount of ketone bodies in the blood Normally the blood contains ketone bodies to the amount of from 13 to 25 mg per hundred cubic centimeters After an operation (usually for calculous cholecystitis) there is a slight increase in the ketone bodies corresponding to the amount of acetone in the urine A slight and decreasing elimination of acetone corresponds to a progressive increase of ketone bodies in the blood The determining cause of the coma in diabetes is not so much the increase in the production of ketone bodies as the appearance of a renal insufficiency permitting the ketone bodies to accumulate in the blood In regard to ketone bodies, the kidneys are divided into three groups (1) normal kidneys with great reserve power, (2) kidneys apparently normal but having slight reserve (could be called "compensated kidneys'), and (3) kidneys without reserve power with already altered function; namely, "decompensated kidneys." Insulin is the specific remedy for ketonemia in decompensation of the kidneys, but if not used at once it cannot save the kidney from irremediable alteration. The behavior of renal function observed in respect to the elimination of nitrogen corresponds perfectly to that of the kidneys in the presence of toxic substances such as ketones. The author concludes that the cause of every accident in cases of postoperative functional insufficiency of the liver can be traced to the kidneys.

*Inflammatory Strictures of Rectum. M. Corachán.—p. 429.

Inflammatory Strictures of Rectum.—From observations made in eighteen patients with inflammatory strictures of the rectum (five men and thirteen women), Corachán concludes that the strictures are consecutive to inflammatory changes in the lymph nodes of the pararectal tissues. The changes in the lymph nodes originate in a primary infection, either genital or anorectal, which in most cases is of the nature of lymphogranulomatosis. Rectitis, which represents the initial stage of development of the inflammatory strictures, is caused by the lymphatic stasis plus a retrogressive infection, provoked by the adenopathy of the lymph nodes and propagated through the lymph chanels. The perianorectal suppuration is caused by septic foci in the regional lymph nodes. Patients with inflammatory strictures of the rectum usually consult the surgeon too late, when the disease is in an advanced stage. As the only treatment of inflammatory strictures of the rectum, the formation of a permanent artificial anus, which the patient can operate at will, seems advisable. When the disease is not yet in an advanced stage and also when the patients do not improve after the formation of an artificial anus, the removal of the distal segment of the sigmoid portion of the colon (which remains after the artificial anus is made) gives satisfactory results. However, if the sigmoid flexure is not included in the pathologic process, its resection is unnecessary. The technic of the operation is simple and the mortality is low.

Polyneuritis Caused by Triorthocresyl Phosphate Poisoning.—From clinical observations made in thirty-seven young women with toxic polyneuritis following the use of apiol as an abortifacient, and also from an anatomic and experimental study of this type of polyneuritis, Carrillo and Ter Braak conclude that the disease manifests itself, after a period of incubation of seventeen days, by sudden development of paralysis of the distal segments of the limbs associated with atrophy of the hands and the feet, disappearance of the achilles tendon reflex, with conservation of the patellar reflex, and absence of disturbances of sensation. The close similarity of the toxic apiol polyneuritis with two other types of toxic polyneuritis (polyneuritis caused by creosote phosphate in the treatment of tuberculosis and the so-called ginger paralysis described in the United States in 1930) made it advisable to classify the three forms of polyneuritis mentioned as included in only one nosologic group. The causal agent in all three forms is triorthocresyl phosphate (which is present in both the ginger extract and in the commercial preparations of creosote phosphate, and apiol). The authors succeeded in reproducing "polyneuritis gallinarum" in a group of chickens after feeding the animals with apiol, obtained from the patients. Paralysis affects the territory supplied by the sciatic nerve. Study of the animals showed that the disease causes great pathologic changes in the muscles, nerves, the genitalia and the liver. The paralyzed territory presents an intense muscular atrophy. The alterations of the nerve fibers, which are of a periaxial and not of a wallerian type, involve selectively the myelin sheath. There are proliferations of the sheath of Schwann and structural alterations of the neuraxis. The changes in the spinal cord are secondary. The poison seems to have a selective action of fixation on the phospholipids and on the distal parts of the nerves, thus causing a direct degeneration of the muscles and, in grave cases, a retrogressive degeneration in the spinal cord. The clinical picture of apiol polyneuritis is dissimilar to the clinical pictures presented by other types of toxic polyneuritis previously reported. It presents only a slight similarity to that of pure phosphorus polyneuritis (caused by phosphorus or its compounds). Patients with both slight paralysis and slight atrophy improve rapidly. When the condition causes great atrophy and intense impotence of the muscles resulting in marked paralysis, the return to normality is slow (between two and three years).

Disturbances of Consolidation Following Orthopedic Osteotomies of Long Bones.—Observations on *621* orthopedic open osteotomies revealed to Brandes the following: 1. In *1.2* per cent of the cases there were disturbances in the healing process, but a pseudo-arthrosis developed in only one instance. *2.* The disturbances in the consolidation were caused by various local changes, such as by a disturbance in the callus formation due to a second surgical intervention at the site of the osteotomy, by bolting of the medullary cavities of the bones of the forearm, by a wire suture of the humerus and by a slight infection of a hematoma on the tibia. In two patients with severely sclerosed old rachitic bones, the consolidation was considerably retarded, and in one instance of Springer's operation the resorption of the wedge led to pseudo-arthrosis. 3. In one case there was no local cause but a gravidity prevented the callus formation. 4. The assumption that not the operative procedures, but rather endocrine disorders are the cause of the retardation in the consolidation, was not confirmed by the author's observations. 5. After osteoclasis he never noted complications or retardation in the healing process. The osteotomy disturbances were most frequent in the leg; dominance of one sex was not noticeable. 6. In the correction of deformities, it should be the aim to obtain results with the smallest intervention.

So-Called Hyaline Thrombosis in Profuse Renal Hemorrhage.—Schwarz relates the clinical history of a patient, aged *24*, in whom on account of life endangering hematuria, chills and severe, colic-like pains in the region of the right kidney, a nephrectomy was done. The microscopic examination revealed a localized thrombosis of the interlobular vessels and of their branches with hyaline fibrin. Subcapsularly, in the region in which the largest number of vessels were thrombosed, there was a wedge-shaped hemorrhagic infarct and several smaller, older infarcts. Where the vessels were not obliterated with the hyaline fibrin, they contained besides fibrin also erythrocytes. The same formations were found in the uriniferous tubules, especially in the junctional tubules and in the collecting tubules. The cause of the formation of this hyaline fibrin remains unexplained, but the author assumes that the erythrocytes participate in its formation and that the casts in the uriniferous tubules may also be formed from fibrin, for morphologically as well as in their staining characteristics the casts are like the thrombi in the vessels.

*Statistics on Lichen Ruber. H. Freund.—p. 57.

Does the Pathogenic Agent of Syphilis Have Other Forms or Stages of Manifestations Besides Spirochetes?—Jahnel and his associates point out that soon after the discovery of Spirochaeta pallida the question arose whether, besides the spiral form, there are yet other forms or stages of the pathogenic agent of syphilis. After reviewing the theories, the authors describe their studies on this problem. They reach the conclusion that although the syphilitic organism can occasionally be demonstrated by vaccination when the microscopic examination does not reveal the spirochetes, this does not justify the assumption that the syphilitic organism is not present in the spirochete form and must therefore be present in the ultravisible form. They believe that the cause of the frequent failures of the microscopic demonstration of the spirochetes is their small number, for they observed that the direct microscopic demonstration fails in blood suspensions in which the spirochete content is below a certain limit; nevertheless by means of these suspensions it is possible to produce a typical infection. They found that if the number of syphilitic microorganisms is less than 300 per cubic millimeter it is no longer possible to detect them in the dark field. As another factor against the existence of an ultravisible form of the syphilis virus they cite the negative results of filtration experiments.

Gumma of Thyroid.—According to Fasal, syphilis of the thyroid, although comparatively rare, may occur during secondary as well as tertiary syphilis. The rarity of syphilitic involvement has been explained on the basis of the iodine content of the thyroid, the iodine protecting the healthy gland against syphilis, whereas the thyroid with impaired function lacks resistance against syphilis. Histologically verified cases of syphilis of the thyroid during the secondary stage are extremely rare. Clinically, the gumma of the thyroid usually presents the aspects of a rapidly growing tumor, which is often sensitive to pressure, which by compression of the trachea and of the esophagus may cause dyspnea and difficulty in swallowing, and which is frequently taken for a malignant struma. However, the literature contains reports also of cases of gumma of the thyroid in which the diagnosis of syphilis was based only on the positive serologic reactions and on the effectiveness of the antisyphilitic therapy. But the author shows that the diagnosis of syphilis of the thyroid is not always justified in cases in which a struma disappears following antisyphilitic treatment, for it has been known that a struma that already existed before the syphilitic infection was influenced by antisyphilitic treatment. Histologically, because of the abundance of giant cells and the frequently pronounced caseation, there is a considerable resemblance to tuberculous granulation tissues. The author describes a case which had several times been diagnosed as malignant struma. However, the positive syphilitic seroreactions and the rapid improvement following antisyphilitic treatment indicated syphilis. Yet this diagnosis could have been made also on the basis of the histologic examination. In discussing the histologic examination, the author mentions and evaluates the various stains and he stresses that the Bielschowsky-Maresch method of impregnation with silver is especially valuable. When this method is employed the gumma always presents a rich meshwork of fresh, fine tissue fibrils without connection with the former stroma, whereas the tuberculous caseation presents only rests of old tissue fibrils.

Statistics on Lichen Ruber.—A statistical review of 1,124 cases of lichen ruber, which were observed during the years from 1914 to 1930, convinced Freund that the incidence of lichen ruber is 20 per cent higher among men than among women. With increasing age the incidence of lichen ruber increases, and it is highest in persons aged between 50 and 60. Seasonal fluctuations were not observed.

Measurement of Skin Temperature During Anesthesia.—Induced by the studies of Ipsen and Foged, who had found that the skin temperature during operations gives indications for the postoperative course, Mayer studied this problem on 196 patients. He found that normally anesthesia increases the skin temperature and that this is most clearly noticeable on the sole of the foot. The increase is due to a dilatation of the cutaneous arteries, especially of the arterioles. Under the influence of ether-oxygen anesthesia, which in some instances was deepened by the administration of a few drops of chloroform, the skin temperature increased on the average by about 5 degrees centigrade. In combined "avertin" and nitrous oxide-oxygen anesthesia, the skin temperature likewise increases by about 5 degrees centigrade. The increase is more rapid than in ether anesthesia. In spinal anesthesia the temperature increase follows immediately after the injection of the anesthetic. Under the influence of local anesthesia, there is as a rule no temperature increase, only occasionally increases from 4 to 6 degrees centigrade being noted. In regard to the prognostic significance of the skin temperature during anesthesia, the author states that an increase (positive Ipsen's anesthesia phenomenon) indicates a favorable prognosis. Deviations from the normal anesthesia reaction (negative Ipsen's anesthesia phenomenon) indicate an unfavorable prognosis.

Pancreatitis Following Operations on Biliary System.—It is pointed out by Popper that the pancreatitis which develops following interventions on the biliary system becomes manifest under various symptoms, none of which are sufficiently characteristic to permit a definite diagnosis. However, with the aid of systematic tests of the diastase content of the blood, it is possible to demonstrate a postoperative disturbance of the pancreas. Since the diastase values return to normal after a certain time, blood sugar tests should be made in order to determine the further course of the disease of the pancreas. If a pancreatic disorder exists, dietary as well as medicinal measures should be resorted to. Insulin should be given, but epinephrine and other medicaments that have a tendency to increase the blood sugar content should be avoided. Continuous drop infusion with sugar solutions is likewise inadvisable. The fact that, of five cases with postoperative pancreatitis, four had a fatal outcome indicates an unfavorable prognosis.

Osteitis Fibrosa and Sarcoma.—It is pointed out by Hoffmeister that in the treatment of osteitis fibrosa it is of greatest significance to consider whether an osteitis fibrosa may develop into a sarcoma, or whether the brown tumors belong in the group of sarcomas. By means of several case reports the author illustrates that the diagnosis osteitis fibrosa has to be made with great caution, for beginning sarcomas may, by changes in their surroundings, simulate osteitis fibrosa. The arrangement of the giant cells does not permit a differentiation between osteitis fibrosa and sarcoma. Roentgen and histologic examinations alone are not decisive. As long as there is no reliable method for the differentiation between malignant and benign changes in the bones, definite rules should be laid down for the surgical treatment. The osteitis fibrosa cystica heals most readily if all the diseased tissue is removed. Moreover, the complete removal of all diseased tissues prevents degeneration into a sarcoma. The following rules should be adhered to in the treatment of osteitis fibrosa, or of a beginning bone disease that resembles osteitis fibrosa: Small cysts should be chiseled out, down into the healthy tissue, and larger cysts should be resected and the resulting defect should be bridged by bone transplantation. If the process is an osteitis fibrosa without sarcomatous degeneration, the subperiosteal extirpation prevents relapse. On the other hand, if there is a sarcoma, the early resection provides the most favorable chances for recovery. The subperiosteal resection has no maiming effect, because the perisoteum regenerates the bone again. The resection can be employed also when the tumor has perforated the bone but has not yet affected the soft parts. If the operation reveals a perforation into the soft parts, the diagnosis sarcoma is established; and only in this case is a maiming operation, such as amputation or exarticulation, justified.

Studies on Postoperative Condition.—Ewig and Klotz, wishing to throw more light on the component factors of postoperative shock, made animal experiments with procedures that are also employed in studies on human subjects. They found that the four conditions that they selected for their studies, namely, central vasomotor paralysis, wound shock, intestinal shock and histamine shock, are conditions of true collapse. However, the pathogenesis of these conditions varies considerably, and consequently their treatment has to be different. The decrease in the amount of the circulating blood, the authors consider the cardinal symptom of collapse. In central nervous collapse it is due to the fact that large quantities of blood are retained in the periphery, but there also develop peculiar changes in the composition of the blood, which in the larger vessels lead to a considerable increase in the plasma, so that the hemoglobin and erythrocyte values decrease considerably. In the peripheral capillary blood, the conditions are reversed. In wound shock and intestinal shock, the decrease in the amount of the circulating blood is primarily due to loss of plasma, so that there is a considerable inspissation of the blood. Since the loss of plasma is mainly due to the escape of plasma in the injured vascular regions, local tissue changes at first predominate in these types of shock. In histamine shock, however, the conditions are more complicated, but they become likewise manifest in a considerable loss of plasma with the resulting inspissation of the blood. In histamine shock in dogs the liver as a storage organ plays an important part, not only in the sense of a filling with blood but also as a result of capillary endothelial injury by escape of plasma into the parenchyma. The latter process, however, involves several other organs. In addition to this there is also a loss of fluid in the stomach and intestine. In the central nervous shock, however, as well as in wound shock and in intestinal shock, a storage function of liver and spleen is not likely. Helpful for the clinical differentiation of various forms of collapse is not only the determination of the amount of the circulating blood, by either the dyestuff or the carbon dioxide methods, but also the determination of its hemoglobin content. Decrease in the amount of circulating blood, with considerable differences in the two methods of determination and decrease of hemoglobin content in arterial and venous blood, indicate central nervous collapse; but if the two test methods of the circulating quantity of blood give similar results and if in addition to this the blood is inspissated, the collapse is of peripheral origin.

Treatment of Pernicious Anemia with Liver and Liver Extracts.—Schlumm thinks that the advantages of parenteral liver therapy far outnumber its disadvantages and that it is superior to enteral therapy. He also suggests that cases that do not yield to enteral liver treatment may yet be saved by parenteral therapy. In comparing several liver extracts that have been used for injection he found that deproteinization reduces the efficacy of the extract considerably. The fact that comparatively small amounts of parenterally administered liver are just as effective as large amounts of enterally administered liver indicates that only a small quantity of the active principle passes the intestinal wall unchanged. This in turn speaks for a hormonal character of the active principle and against the theory that the liver becomes active by absorbing toxins. If the active substance really is hormonal the deficiency theory of pernicious anemia seems more probable, the more so because pernicious anemia seems to be related to other deficiency diseases, such as sprue, beriberi and pellagra.

Accelerating Action of Parathyroid Hormone on Coagulation.—Following investigations, Bume and Werber became convinced that, besides increasing the calcium content of the blood, the parathyroid hormone also effects an increase in the thrombokinase; they think that to this influence on the thrombokinase can be ascribed the superiority of the parathyroid hormone over calcium therapy in the treatment of hemoptysis.

Rhinopathia Vasomotoria and Digestive Disturbances.—Adlersberg and Forschner show that the etiology of rhinopathia vasomotoria is not always the same. In the majority of cases it is of allergic origin, in a second group it is enterogenic, and the third form is closely connected with the internal secretions. In this paper the enterogenic form is discussed primarily. In a large rhinologic material the concurrence of typical rhinopathia vasomotoria with gastro-intestinal disturbances was observed in thirty-six patients. On the other hand, among a large number of patients with gastro-intestinal disorders, thirty-three were discovered in whom there also existed a rhinopathia vasomotoria. The enterogenic form of rhinopathia vasomotoria usually shows the following characteristics: (1) simultaneous existence of typical gastro-intestinal symptoms (usually chronic enteritis or colitis), (2) modification of nasal disorders by treatment of gastro-intestinal disturbances, and (3) absence of allergic symptoms (especially absence of eosinophilia in blood and tissues). The authors call attention to connections between rhinopathia vasomotoria and oxyuriasis, and to relations with incretory processes as well as to the influence of the intestine on the allergic form of rhinopathia vasomotoria.

Dermatitis Bullosa Caused by Plant Poison. L. Haymann.—p. 874.

Therapy of Effusions and Vascular Disturbances in Extremities.—Schede and Bettman point out that circulatory disturbances of the extremities and chronic effusions of the knee joint are frequently refractory to treatment, particularly when the causes are not known. Yet it is important to remove the effusion before a flail knee or an arthrosis deformans develops; and chronic circulatory disturbances of the leg should at least be improved to such an extent that chronic indurations, ulcers and thrombophlebitic changes are avoided. The authors describe methods of mechanical treatment that are helpful in realizing these aims. The impaired circulation can be improved by rhythmic opening and closing of the arterial blood stream, by means of vascular massage or compression. Vascular massage is done by alternately inflating and deflating a rubber tube that is put around the thigh. This treatment influences not only the limited region but the entire peripheral vascular system. On the same principle of rhythmic compression are based the inflatable rubber stocking and the inflatable abdominal bandage, and they are used for the same purpose, namely, that of stimulating the circulation or, in the case of the abdominal bandage, for improving the thoracic respiration in patients with spondylosis. In addition to the vascular massage the authors recommend gymnastic exercises, hydrotherapeutic measures and medicinal treatments. In discussing gymnastics they mention bicycle exercises, various forms of knee bending, and turning in bed without using the arms. Hydrotherapeutic measures aim to improve the circulation by thermic stimulation, such by cold showers applied from the toes upward to the waist; also by alternating hot and cold foot baths and by subaqual massage. For the medicinal treatment the authors recommend measures that dilate the capillaries and the arteries.

Dietary Alteration in Infectious Diseases.—Friedrich shows that, by a sudden change in the diet, reactions may be produced in the course of infectious diseases, which, in persons with slight fever become manifest in a primary (not always recognizable) increase in temperature with subsequent decrease or only in a temporary decrease. The direction of the dietary change whether from acid to alkaline or in the reverse direction seems to be of slight significance; not the type but the suddenness and intensity of change is the decisive factor. Whereas the reactions that are produced by changes in the diet are almost the same in the various types of diet, the prolongation of a one-sided diet produces a characteristic action such as an increase in temperature by a diet inducing acidity, a decrease by a diet inducing alkalinity. Regular repetition of a change in diet in definite intervals is capable of influencing the course of infectious disease favorably, in that it has a defervescent effect. In patients with slight fever the author noted a favorable influence when the diet was changed after intervals of from one to two days. Less frequent changes were less effective. In patients with high fever the change should, if possible, be still more rapid. The author considers the change of diet as a promising method to influence patients with infectious and other diseases.

Extirpation of Spleen and Blockage of Reticulo-Endothelial System in Experimental Tuberculosis.—Owing to the fact that administration of spleen preparations have proved of favorable influence on tuberculosis in guinea-pigs, and because the action mechanism of this spleen therapy has not been understood as yet, Subin decided to approach the problem of the rôle of the spleen in tuberculosis from a different angle, namely, by subjecting tuberculous rabbits to splenectomy, and also by blockage of the reticulo-endothelial system with colloidal dyestuffs. It was found that splenectomy has an unfavorable influence on the course of tuberculosis, for the rabbits subjected to it showed more extensive tuberculous processes of a primarily exudative character than those that were not splenectomized. However, the blockage of the reticulo-endothelial system had the opposite effect of what was expected in view of the effect of the splenectomy, for in splenectomized animals in which the reticulo-endothelial system was blocked for a prolonged period the tuberculous lesions were much less severe than in the animals in which only splenectomy was performed. The author thinks that this favorable effect of blockage is due to the fact that it does not injure the reticulo-endothelial system but, on the contrary, that the dye-stuff has a stimulating effect.

Zentralblatt für Chirurgie, Leipzig

Rupture of Axillary Artery in Shoulder Luxation. H. Schirmer.—p. 1433.

Treatment of Intestinal Paresis by Means of Infusions of Hypertonic Sodium Chloride Solutions.—Keusenhoff considers as particularly valuable a method that has been recommended by French authors, who were able to counteract postoperative paralytic ileus by intravenous injection of 15 cc. of a 20 per cent solution of sodium chloride. The infusion not only effects a contraction of the smooth muscles but also aids in the elimination of the toxic substances that have accumulated in the tissues. The author employed this method in a number of cases of intestinal paresis that developed following laparotomy. When after thirty-six hours the usual procedures do not succeed in stimulating the inactive intestine, from 10 to 20 cc. of a 10 per cent solution of sodium chloride is injected. Care should be taken that the injection is not made paravenously, which would lead to painful infiltration. In mild cases the effect is usually prompt; if it is retarded, from 125 to 150 cc. of a 20 per cent solution of sodium chloride is given by rectum. The treatment with sodium chloride solution also proved helpful in ileus-like conditions that develop in diseases of the uropoietic system. He illustrates this with two case reports. In cases of intestinal paresis that have an organic cause, the described treatment is of course without effect; in instances in which the diagnosis is uncertain, it is advisable to give the injection of the hypertonic sodium chloride solution only in the clinic, so that no time is lost if a surgical intervention becomes necessary.

Erythrocyte Sedimentation Speed and Leukocytes.—Heimann thinks that it is now a matter of course to determine in clinical patients not only the erythrocyte sedimentation speed but also the leukocyte picture. After mentioning the numerous factors that have to be considered in determining the sedimentation speed of erythrocytes, he discusses the leukocytic hemogram and the number of leukocytes. He emphasizes that in sedimentation as well as in the leukocytic hemogram a single examination is not sufficient but that the tests have to be repeated from time to time. The sedimentation and the leukocytic blood picture frequently show in the beginning a contradictory behavior; for instance, the sedimentation is rapid and thus characteristic for an acute inflammation, whereas the leukocyte count, which in an acute inflammation would be expected to be high, is extraordinarily low. This observation induced the author to watch for it in his studies on fifty patients with gynecologic disorders. He describes only a few of the cases examined, but these indicate what he observed in the large number; namely, that the sedimentation speed, the number of leukocytes and the leukocytic hemogram, when they are studied alone, give only an unclear picture of the processes in the organism and are not an entirely reliable basis for the prognosis. However, the comparison of the three tests gives valuable information about the prognosis, or whether an operative intervention is necessary or not.

Conservation of Genital Function Following Irradiation for Uterine Carcinoma.—It is pointed out by Philipp that irradiation of genital carcinomas usually results in functional exclusion of the ovaries and of the uterus. This applies to roentgen rays as well as to radium rays. In the case of roentgen rays this is understandable since the carcinoma dose is several times as large as the castration dose, but this is not equally true of radium, since the effective rays of radium are less far-reaching; but even here the dose that heals the carcinoma is generally sufficient to exclude the ovarian function, for nearly all patients who were treated with radium became amenorrheal and remained so. Patients in whom menstruation persists following radium irradiation are exceptions. Among 250 women with genital carcinoma who were cured by irradiation, there were only two who subsequently became pregnant and in two others menstruation persisted. In trying to explain this conservation of function, the author points out that it may be due to the fact that the ovaries were too far away from the radium so that its rays were not sufficiently strong to impair the function, or the dosage may be of influence.

Experimental Study of Cataract.—Using rabbits as experimental animals, Rodigin studied the composition, cytology, proteolytic and amylolytic ferments and the histology of the *aqueous humor of the anterior chamber of a normal eye and* an eye with experimental cataract. His conclusions are as follows: During the resolution of cataracts experimentally produced by intracapsular injection of 8 per cent solution of magnesium chloride, there is a change in the morphology of the aqueous humor with a predominance of lymphocytes and phagocytosis with inclusion of masses of the crystalline lens. When the absorbing process ceases, the morphologic picture of the aqueous humor becomes almost normal. Besides the morphologic changes there is also an increase in the proteolytic and amylolytic ferments. Under normal conditions the aqueous humor possesses an index of 8.3 for protease at 14 C. and 12.5 for protease at 38 C. and an index of 20 for diastase; whereas, in the presence of a swelling and a resolving cataract, both ferments increase and the index becomes 50 for protease and 80 for diastase. Stabilization of the cataract leads to a decrease in ferments with a disappearance of cellular elements. These results agree with the pathologico-anatomic observations. During resolution of the cataract, the cellular elements appear also in the posterior chamber and in various regions of the crystalline lens. The intra-ocular flow is toward the ciliary process and the phagocytosis is demonstrated during the passage of the crystalline substance to the ciliary process. The author does not believe that the changes occurring in the rabbit's eye can be compared in toto to the human eye, but analogies can nevertheless be drawn.

*Course of Complement Binding in Gonorrheal Infection in Women. V. Genner, K. Antons and H. Boas.—p. 633.
Vitamin E and Vitamin E Therapy in Animals and Man. P. Voght-Møller.—p. 663.

Complement Binding in Gonorrheal Infection in Women.—Genner and his associates found a much less marked complement binding reaction in women with gonorrhea in whom the infection was limited to the cervical canal than in those in whom the oviducts also were affected, the difference being so considerable that a marked reaction, they say, may justifiably, in spite of the absence of clinical symptoms, be regarded as pointing to disease of the oviducts, and the more protracted the reaction, the more justifiable is this point of view. A persistent marked and positive complement binding reaction is due to latent foci, and the adnexa probably afford far better conditions for a retained inflammatory process than do the endometrium and cervical canal.

THE CRISIS IN PSYCHIATRIC EDUCATION

CHAIRMAN'S ADDRESS

FRANKLIN G. EBAUGH, M.D.
DENVER

During the past year I have had the privilege of conducting an inventory and appraisal of psychiatric teaching facilities as a part of the activities of the Division of Psychiatric Education of the National Committee for Mental Hygiene.[1] This work was planned under the direction of an outstanding advisory committee, of which Adolf Meyer is chairman. It is based on actual visits to each school which covered a study of the facilities for psychiatric teaching, with interviews with the teaching staff in psychiatry, the deans and administrative officers, professors of medicine and professors of pediatrics. Additional information showing the attitudes of students and recent graduates has likewise been obtained from many schools. I should like to present a part of the factual data accumulated to date and summarized for the first sixty schools visited. These data, although discouraging in some respects, show that psychiatric education is rapidly developing in this country and that representatives of all the fields of medicine are cognizant of the problems of psychiatric education and of the importance of meeting the ideal of medical education, which should be to graduate students capable of intelligently practicing medicine.

The word "crisis" comes from the Greek word meaning "to separate." It also is used commonly to mean an important or crucial point. In medicine it is used to mean that change in a disease which indicates whether the result is to be recovery or death. Fortunately, psychiatric teaching is not in this position, but it seems to me that the word "crisis" could be used to indicate the crucial point that now confronts the teaching of psychiatry, as at the present time many noteworthy and significant changes are being developed which indicate a departure from the past standards in which a majority of the medical schools paid little attention to the teaching of psychiatry, usually presenting this work during the latter part of the senior year when the students are often not interested and have not been prepared to see the significance of the work as a part of their fundamental preparation for all medicine. The courses given in the past have usually been isolated from the other fields of medicine or consisted of a one day visit to a state hospital or institution for the feebleminded, along with a square meal and a vaudeville show for the students.

It was of great interest to me to know that the chairman's address before this section in 1914 was entitled "Some Factors Tending Toward Adequate Instruction in Nervous and Mental Diseases."[2] Dr Graves, in his address, spoke of a standard medical curriculum allotting one hundred and fifty hours in the clinical years to neurology and psychiatry; sixty hours in the third year to neurology, and ninety hours in the fourth year, of which fifteen hours were devoted to clinical conferences and fifteen hours to didactic lectures in psychiatry. In practically all schools at that time neurology and psychiatry were combined in one department and in approximately one half of these schools this combined department was independent of medicine. In the study made by Dr. Graves of the curriculum of eight-five schools, he stated:

> The tabulation shows specific defects in the following particulars: first, that 5 out of 85 schools give no instruction whatever in either neurology or psychiatry; second, that as far as can be determined from the catalogs, neurology and psychiatry are combined in instruction under the collective terms "nervous and mental diseases" in 25 of the remaining 80 schools; third, that of the 55 schools teaching neurology and psychiatry in separate courses in both third and fourth years, 27 . . . give a place to neurology and only 2 to psychiatry; fourth, that whereas in these 55 schools 32 teach neurology, only 2 teach psychiatry in the third year; yet in the fourth year 47 teach neurology and 42 teach psychiatry; fifth, that the average total hours allotted to the department of nervous and mental diseases in the schools of each class is much less than the total hours recommended in the standard curriculum.

THE PSYCHIATRIC CURRICULUM

The general situation in psychiatric education in 1932 is quite different and may be summarized as follows:

An analysis of the psychiatric curriculum in the sixty schools visited is of interest. Psychiatry functioned as a separate department in nineteen schools, as a department combined with neurology in fifteen schools and as a subdepartment of medicine in twenty-five schools.

In contrast with the former tendency to present psychiatry chiefly during the senior year, at the present time twenty-eight schools are engaged in teaching psychiatry during the preclinical years; thirty-one limit it to the clinical years, of which eleven schools present psychiatry during the fourth year only. One school limits its psychiatric teaching entirely to the third year.

Read before the Section on Nervous and Mental Diseases at the Eighty-Third Annual Session of the American Medical Association, New Orleans, May 12, 1932.

[1] Dr. C. M. Hincks, general director of the National Committee for Mental Hygiene, and Dr. Ralph A. Noble, director of the Division of Psychiatric Education, allowed me to use this material.

[2] Graves, W. W.: Some Factors Tending Toward Adequate Instruction in Nervous and Mental Diseases, J. A. M. A. 63: 1707-1711 (Nov. 14) 1914.

and one school does not offer it at all. Elective work is offered in seventeen schools. The total hours devoted to the teaching of psychiatry were four thousand one hundred and thirty-seven; the average hours devoted to the teaching of psychiatry in each school were sixty-eight and eight-tenths. The variation in the number of hours was from a maximum of two hundred hours to a minimum of sixteen hours.

These findings and contrasts with those reported by the chairman of this section in 1914 indicate clearly a crucial turning point in psychiatric education. For instance, the majority of schools then presented psychiatry during the fourth year only, but many are now teaching psychiatry during the preclinical years. Graduate and elective work were universally neglected in 1914. The content of the psychiatric curriculum is of interest. In the teaching reported during the preclinical years, eleven schools are now presenting courses in psychobiology. Psychobiology is defined by Meyer as: "a science of personality-formation and personality-function, objective and yet reflecting all of man's subjectivity, keeping close to a common ground of generally accessible facts and concepts. Using a pluralistic natural history formation and making the necessary realignment of the sciences, psychobiology aims to bring together the physician and all those who work with human beings and to effect a division of labor in harmony with the concept of integration, with interpenetration rather than overspecialization." These courses are usually given during the first year. Eleven schools give courses in medical psychology which serve as an introduction to the clinical years, and fifteen schools give introductory courses in psychopathology. In 1932 the tendency in the teaching of psychiatry during the clinical years is to do away with didactic instruction, replacing it with teaching by clinics and clerkships and outpatient work. A discussion of the psychiatric curriculum will be presented later.

ANALYSIS OF CLINICAL FACILITIES FOR PSYCHIATRIC TEACHING

During the past decade better facilities have developed for psychiatric teaching. For instance, at the present time there are twelve psychopathic hospitals or institutes utilized by eighteen schools for teaching. These hospitals are well equipped for the teaching of psychiatry, with excellent ward facilities for the proper care of the patient, centering around a complete staff, adequate nursing and hydrotherapeutic facilities, occupational therapy and consultation and social service and outpatient facilities, including clinics for children. One is pleased to note that seventeen state hospitals are utilized for teaching. Psychopathic wards, frequently inadequate, are utilized for teaching in eighteen schools. Outpatient departments are available and utilized for teaching in forty of the sixty schools studied. In approximately one half of these schools, however, these facilities were considered inadequate for teaching. The outpatient departments were not available or utilized in the remaining twenty schools. It is also of interest to note that an excellent psychopathic ward of the United States Penitentiary at Atlanta, Ga., is used for teaching as well as two Veterans' Bureau hospitals. In many instances psychiatric facilities have been made available during the past two or three years, and since 1930 five medical centers have developed complete facilities for psychiatric teaching and research. In teaching schedules the past few years have seen the development of psychiatric clerkships and a gradual development of outpatient teaching. It is of interest to note that seven medical schools require a residence of from one to two weeks in a state hospital. This is a pleasing development in psychiatric education, as it enables the student to familiarize himself before graduation with the many problems offered by a state hospital and so to develop a sympathetic attitude. This teaching should, of course, be complemented by preclinical teaching.

It is obviously important for students to come in contact with the many clinical problems found in state hospitals. Many of these hospitals now have excellent reception services that are far superior to those the universities have to offer. I hope that in the future state hospitals will be used more for teaching. Students should be given regular summer assignments to those hospitals. No teaching organization should overlook the state hospitals.

The total budget for the teaching of psychiatry in the sixty schools is $360,000, and twenty-three of these operate on a full-time or part-time basis. Of this group, there were only seventeen operating on a full-time basis.

Interviews with professors of psychiatry in terms of their objectives of teaching may be stated as follows:

Aside from the necessity of giving the student the basis for recognition of the main reaction types, the major trend in teaching is the effort to prepare the student for the psychiatric conditions commonly encountered in general practice. As a corollary to this is stressed the importance of early recognition of mental illness and the principles of mental hygiene. So-called preventive measures are widely taught. From this broad basis there are many departures into progressive teaching, such as preclinical instruction in psychobiology and psychopathology (twenty-seven schools), both of which aim to ground the student soundly in the psychology of personality in health and in disease; advanced courses (frequently elective) to meet the needs of the student with special interest; special attention to the psychoneuroses, and the recognition of the need for better training of psychiatrists. On the red side of the ledger is the frank admission of no "real attempt to teach psychiatry" in one school, while in another the aim is solely to enable the student to pass state board examinations. Several schools continue to labor under the influence of the organicists to the exclusion of the modern psychiatric thought and a few more limit teaching to the barest outline of the classic types. These are in line perhaps more with contemporary legal formulas than with scientific progress. However, it was interesting to note that in the interviews with those held responsible for the teaching of psychiatry the predominant point of view may be described as genetic-dynamic, in which mental disorders are considered to result from the gradual accumulation of unhealthy reaction tendencies to life's situations. A genetic-dynamic study, therefore, means the study of all previous experiences of the patient, the total biography of the subject and the forces he may be reacting to, whether physical, organic, psychogenic or constitutional. The emphasis is placed on mechanisms and forces at work instead of on diseases by this group of psychiatrists, which is in contrast to the kraepelinian type of psychiatry based on classifications, profuse descriptions of symptoms and disease entities.

In discussions with the professors of psychiatry in various schools, the following trends for future psychiatric teaching were noted:

1. Establishment of psychiatric hospital units in general hospitals.
2. Establishment of separate departments of psychiatry, adequately budgeted.
3. Establishment of a full-time or part-time teaching personnel.
4. Integration of psychiatry with other medical teaching.
5. Increase in number of curriculum hours with introduction of preclinical subjects such as psychobiology, psychopathology, etc.
6. Better utilization of outpatient facilities and the establishment of psychiatric clerkships.
7. Establishment of child guidance clinics in conjunction with teaching hospitals and their utilization in the teaching program.
8. Establishment of extramural psychiatric clinics and community programs.

Interviews with the deans of the schools visited may be summarized as follows:

Deans having a sympathetic attitude, fifty-four.

Deans having an unsympathetic attitude, six.

Criticisms of psychiatry (listed in order of frequency): lack of integration, isolation; inadequate personnel; varying terminology; inexactness; therapeutic inefficiency.

"I think it (psychiatry) is a most important clinical subject today. You can't train any physician for medicine unless he has some fundamental understanding of the personality approach to the patient."

This summary emphasizes the characteristic complaint that psychiatry has been too isolated from the other divisions of the medical curriculum according to the comments of the majority of the deans who have been interviewed.

The attitudes of the professors of medicine, as follows, indicate a similar trend, with marked emphasis on the frequency of the psychoneuroses and difficulties in establishing satisfactory treatment of this group:

Uniform interest in psychiatry.

An estimate as to the incidence of psychiatric problems ran from 2 to 75 per cent, with a median of 35 per cent.

SURGERY and its SPECIALTIES
PEDIATRICS
OBSTETRICS and GYNECOLOGY

Chart 1.—Proposed functional relationships of psychiatry and integration with major divisions of the medical curriculum.

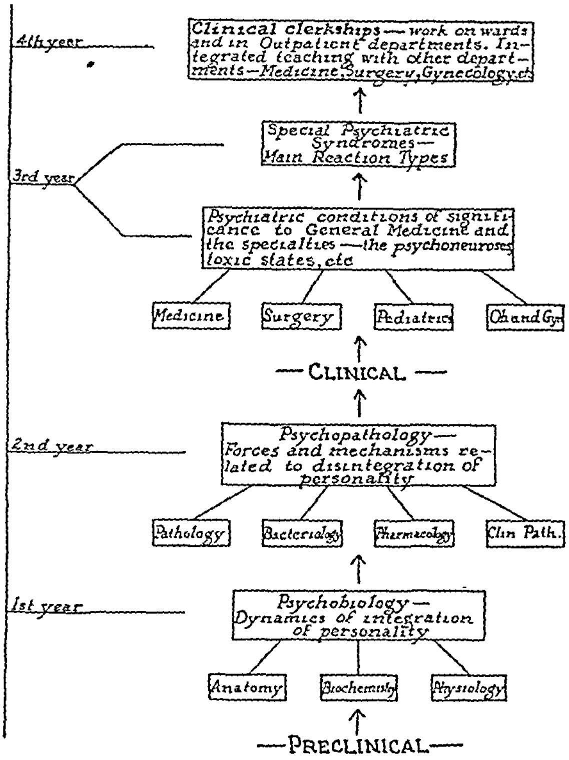
Chief criticisms (listed in order of frequency): isolation, lack of integration; inadequate personnel; varying terminology.

"It seems to me that adequate psychiatric teaching is the biggest reconstruction that can occur in present-day medicine."

Likewise, the attitudes of the professors of pediatrics interviewed in these schools indicate an awakening of interest in problems of behavior which cannot help but be significant in improving the work in all fields:

Uniform interest in psychiatry as it pertains to their own field.

Incidence figures as to psychiatric cases in pediatrics run from 10 to 70 per cent, with a median figure of 30 per cent.



4th year
Clinical clerkships—work on wards and in Outpatient departments. Integrated teaching with other departments—Medicine, Surgery, Gynecology, etc

—PRECLINICAL—

Chart 2.—Proposed outline for psychiatric teaching.

Chief criticisms (listed in order of frequency): inadequately trained personnel; lay workers in field of child guidance and mental hygiene; variation and obscurity in psychiatric nomenclature; isolation, particularly of child guidance clinics.

The majority (two thirds of those interviewed) feel that child guidance clinics should be associated with teaching hospitals and should be the joint responsibility of pediatrician and psychiatrist. One third feel that child guidance should be the province solely of the pediatrician.

One notes the reasonable criticisms regarding the frequent lack of adequate training of the personnel in psychiatry. The main problem of psychiatric education is to attract more men into this interesting field and to see that they acquire proper training. The requirements for postgraduate training should be most carefully considered, and at least five years should be spent in psychiatry following the preparatory rotating intern period. This five year period of training can be made possible through fellowships and should include all divisions of psychiatry, especially child psychiatry. In the visits made to the various schools the need for trained personnel was found to be very great in many centers, both to augment the teaching staff and for hospital and private work. The situation that now confronts psychiatry in the lack of personnel in this field is similar to that which confronted pediatrics a decade ago. We hope that our field will solve this problem as well as it was solved by the pediatric group.

The foregoing factual data centering around the attitudes of the professors of psychiatry and members of the teaching staff, the deans, professors of medicine and professors of pediatrics, indicate to me that there are two distinct phases of psychiatric teaching, undergraduate teaching and postgraduate training for the specialty of psychiatry. By far the more important of these is the first, and psychiatry is therefore not to be looked on merely as a specialty but as a part of the fundamental training of every medical man. Those outside of the field who have given considerable thought to these problems feel that the effectiveness of psychiatry has been injured by its isolation. In many respects we ourselves have been responsible for this isolation.

Chart 1 indicates to me possible measures for the integration of psychiatry in relation to the four major divisions of the medical curriculum.

It is to be seen in chart 1 that the first four topics are clinical, and the fifth topic, interdepartmental and liaison activities, is administrative and calls for combined clinics with each field. These combined clinics mean not only a breaking down of the isolation and of greater integration with psychiatry, but also a getting-together principle which should react well to both fields, especially in terms of establishing the treatment of the whole patient. Through such an integration of psychiatry with the other four fields we can expect the future internist, the surgeon, the obstetrician and the pediatrician to have a reasonable understanding of mental reaction types, especially the psychoneuroses, and to be able to evaluate mental symptoms (to the extent of at least recognizing the early stages of a delirious reaction and avoiding excessive use of sedatives). Mental hygiene and mental health issues must always be considered by the adequately trained physician in all fields.

Chronological Table of the Development of Psychiatric Teaching in the United States

The Past		*The Present Crisis*	*The Future*
Up to *1918*	From *1918* to *1930*	From *1931* to *1932*	
Psychiatry in Isolation	The Break-Down of Isolation		The Completion of the Integrating Program
1 Teaching largely in terms of the insanities 2 Teaching didactic, descriptive, limited to clinical years 3 Mental hospitals separated from the universities 4 Growth of asylums and the custodial idea 5 Inadequate teaching personnel 6 Nihilistic attitudes regarding therapy 7. Dominance of organic point of view 8 Lack of interest from students and faculties	1 Emphasis on psychiatry as a fundamental part of general medical training 2. Introduction of psychiatry into the preclinical curriculum 3 The acceptance of genetic dynamic principles 4 Greater interest in the preventive idea mental hygiene, child guidance, community programs 5 Emphasis on psychotherapy, psychodynamics, break down of therapeutic nihilism 6 Growth of integrative idea, correlating psychiatry with other divisions of medical teaching 7 Development of clinical research 8 Development of trained personnel 9 Growing interest on part of students	Period of Inventory and Reorganization The development of adequate teaching requirements for the fundamental training of all physicians and the organization of scientific and economical means of meeting the medical, social and individual problems of mental illness	1. Complete integration under the same roof psychiatric beds in the general hospital 2. Psychiatric principles applied to the management of the sick under the total personality concept 3. The development of liaison activities with other departments of medical teaching 4. The development of psychotherapeutic clinics and institutes of research in the universities ' 5 Establishment of full time or part-time teaching personnel 6. Closer integration with public health and preventive medicine 7. Establishment of behavior clinics in close correlation with teaching hospitals and the departments of pediatrics 8 Establishment of extramural clinics and community programs for the care of the mentally ill 9. Elimination of the custodial hospitals as isolated units 10. Establishment of requirements for the specialty of psychiatry through a board of qualified examiners approved by the American Psychiatric Association and organized by the National Board of Medical Examiners

In terms of furthering this essential integration with psychiatry I should like to propose a provisional curriculum that emphasizes the importance of presenting psychiatry during each of the four years of medicine with special emphasis on the psychoneuroses (the minor psychoses) (chart 2).

The facts that every medical man should know regarding the major psychoses are to be presented, although detailed psychopathologic studies are not considered necessary here since they are a fundamental part of postgraduate training. It will be seen in the proposed outline that practically all of the preclinical work constitutes what is necessary for further training in psychiatry as well as what is equally necessary as a part of the training for all medicine. This scheme is not presented in terms of number of hours, although for purposes of orientation they have been inserted. It does not call for additions to the total curriculum as much as a redistribution of hours, and other departments have often expressed a willingness to give up hours to psychiatry. I would deplore very much any efforts for standardization of a psychiatric curriculum. The number of hours is of little importance compared to the training of the teacher, the methods and content of teaching and the clinical facilities available for individual case study by the student.

COMPARISON OF REACTIONS OF STUDENTS WITH REACTIONS OF RECENT GRADUATES

As a part of this study and inventory of present-day psychiatric education the following summary has been prepared contrasting the attitudes of 800 undergraduates with 152 recent graduates, chiefly comprising the present intern and resident group:

Summary on Eight Hundred Undergraduates.—The following questions and answers were given:

1. Do you feel interested in the applications of psychiatry to general medicine? Indicate reasons for your interest

Yes, 756 or 94.25 per cent. No, 44 or 5.75 per cent.

2. Has your *instruction* in psychiatry been a material factor in this interest? (*a*) Slight? (*b*) Moderate? (*c*) Large? If so, in what manner?

(*a*) 176 or 22 per cent. (*b*) 376 or 47 per cent. (*c*) 248 or 31 per cent.

3. Do you feel that you understand what is meant by psychotherapy, so that you could use its principles in the treatment of patients? (*a*) No, or very little? (*b*) With reasonable chance of benefit? (*c*) With considerable confidence?

(*a*) 308 or 38 5 per cent. (*b*) 444 or 55.5 per cent. (*c*) 48 or 6 per cent.

4. Do you feel that your psychiatric instruction has given you adequate practical knowledge of the psychoneuroses, their genesis, prevention and treatment? (*a*) Insufficient? (*b*) Reasonably sufficient? Indicate any material deficiencies.

(*a*) 320 or 40 per cent. (*b*) 480 or 60 per cent.

5. Do you feel that you understand the principles involved in mental hygiene, from the point of view of their practical application? If so, to what extent? (*a*) No, or very little? (*b*) With reasonable understanding? (*c*) With special interest?

(*a*) 288 or 36 per cent. (*b*) 472 or 59 per cent. (*c*) 40 or 5 per cent.

Summary on One Hundred and Fifty-Two Graduates.—The following questions and answers were given:

1. Do you feel interested in the applications of psychiatry to general medicine? Indicate reasons for your interest.

Yes, 147 or 97 per cent. No, 5 or 3 per cent.

2. Has your *instruction* in psychiatry been a material factor in this interest? (*a*) Slight? (*b*) Moderate? (*c*) Large? If so, in what manner?

(*a*) 63 or 41.5 per cent. (*b*) 63 or 41.5 per cent. (*c*) 26 or 17 per cent.

3. Do you feel that you understand what is meant by psychotherapy, so that you could use its principles in the treatment of patients? (*a*) No, or very little? (*b*) With reasonable chance of benefit? (*c*) With considerable confidence?

(*a*) 69 or 45 per cent. (*b*) 77 or 50 per cent. (*c*) 6 or 5 per cent.

4. Do you feel that your psychiatric instruction has given you adequate practical knowledge of the psychoneuroses, their genesis, prevention and treatment? (*a*) Insufficient? (*b*) Reasonably sufficient? Indicate any material deficiencies.

(*a*) 87 or 57 per cent. (*b*) 65 or 43 per cent.

5. Do you feel that you understand the principles involved in mental hygiene, from the point of view of their practical application? If so, to what extent? (*a*) No, or very little? (*b*) With reasonable understanding? (*c*) With special interest?

(*a*) 69 or 45 per cent. (*b*) 78 or 51 per cent. (*c*) 6 or 4 per cent.

In general, it may be said that there is a frequent correlation between the answers to questionnaires and the evaluations as to teaching adequacy made in this report. One school, in which there is admittedly no real attempt to teach psychiatry, demonstrates this very well in that only four of twenty-nine students thought their teaching in psychiatry adequate.

On the whole, the questionnaires have been well received, and many interesting comments have been received from students. The interest in psychiatry is quite uniform, but there is great variation in answers to questions grouped under 3 and 5. One student from Yale thought the questionnaire ridiculous. Perhaps the most significant figure obtained is in group 4, in which 40 per cent of the students considered their psychiatric training insufficient to their needs.

OPINION CONCERNING APPRAISAL OF SCHOOLS VISITED

In terms of an inventory and appraisal of the sixty schools visited to date, sixteen were considered to offer adequate teaching in psychiatry. This tentative appraisal was made on the basis indicated, that is, the teaching personnel, the method and content of psychiatric teaching and the clinical facilities available. It is quite encouraging to realize that in ten of the remaining schools one would estimate that adequate teaching will develop rapidly in the immediate future. In fact, during the year of this study one school has established adequate teaching, although the course was definitely inadequate during the previous school year.

GENERAL COMMENT

In a limited presentation of this type one is forced to pick out the outstanding factual material concerning psychiatric education. It is not possible to give in detail a description of the content of the teaching curriculum or to report on characteristic local set-ups and situations in psychiatry which must always be carefully evaluated.

There is a challenge given to all medicine in the present situation. We have certainly reached a crisis in psychiatric education, which in terms of chronological relationship, beginning with the revival of interest in psychiatry during the war, may be illustrated by the accompanying table.

This crisis in psychiatric education is a part of the general crisis in medicine today, in which we all recognize changing attitudes of the relation of the physician to society. In these changing attitudes the public demands a greater recognition of the important part social forces play in the activities of the individual as well as continued scientific achievement in preventive medicine. Mental hygiene may be considered a very important part of preventive medicine. The way we meet this crisis in psychiatric education and the part that psychiatry will play in the development of medicine in the future will decide the degree of social usefulness and therapeutic efficiency of the physician in general. The contributions of psychiatry, like those of preventive medicine, should soak through the whole curriculum. This will mean a type of training that will result in the treatment of the total patient by graduates of medical schools. This total patient has a mind as well as a body. "Mind is the human being in action," and this action is spoken of as behavior, which is just as important a part of the clinical study of a patient as the understanding of physical problems, and the two cannot be separated.

MEDICAL TEACHING IN TUBERCULOSIS

BENJAMIN GOLDBERG, M.D.
Associate Professor of Medicine, University of Illinois College of Medicine
CHICAGO

AND

JESSAMINE S WHITNEY
Statistician, National Tuberculosis Association
NEW YORK

At the meeting of the International Union Against Tuberculosis at Oslo, in 1930, one entire day was given over to a discussion of medical teaching in tuberculosis. In view of the fact that this subject is gaining greater importance, a study was undertaken to determine its status in the United States.

On reviewing the statistics which have been compiled, one observes that tuberculosis mortality has decreased in this country to a point at which its rate in 1931 was 67 per hundred thousand. This is one third of the rate that existed in 1904, and during these twenty-seven years tuberculosis has dropped from first place to seventh place as a cause of death. At the present time this disease takes its greatest toll of life between the ages of 15 and 45, and between these ages it still heads the mortality list. This in itself calls for continued consideration of the educational aspects of this very vital subject.

Two problems immediately present themselves; viz., the medical problem and the public health problem. From the medical standpoint it is essential to appreciate that the final favorable result is dependent in no small measure on the early diagnosis of the disease. On the other hand, from the public health standpoint, a late diagnosis delays supervision and control and makes possible increased dissemination of the infection in the community.

During the year 1930, in the public clinics of the five large cities enumerated in table 1, 11,782 individuals were diagnosed for the first time as having tuberculosis. The table gives the stages of this disease and also the percentage of patients in the various stages as they have been found in these communities and in the total.

From an analysis of these statistics it is obvious that in 70 per cent of these patients the disease had progressed to a stage, moderate or far advanced, lessening the opportunity for recovery. The community likewise has been subjected to the possible hazard of uncontrolled infection.

Table 1.—*Stages of Tuberculosis in Persons of Five Cities*

	Minimal Incipient		Moderately Advanced		Far Advanced

Philadelphia	964	27	1,427	40	1,178	33	3,569
Los Angeles*..	38	9	212	40	168	51	418
Totals..	3,551	30	4,914	42	3,317	28	11,782

* Do not show stage on nonactive pulmonary cases.

Has the lay education, conducted continuously for twenty-six years, failed to bring a response from these patients so that they did not present themselves for a timely diagnosis? While this is true in some instances, there are those patients who have presented themselves, and for whom a correct diagnosis was not made until the disease had progressed beyond the minimal stage. On this assumption we have for some time made the statement, "if we are to educate lay individuals to suspect a disease, the medical practitioner must be able to confirm or remove that suspicion."

TEACHING OF TUBERCULOSIS IN THE UNITED STATES

To determine the status of medical teaching in tuberculosis in the medical colleges in the United States, questionnaires were sent to these institutions. There are sixty-six approved colleges which offer a complete curriculum in medicine. Sixty-four of these colleges returned their questionnaires more or less completely filled out. The data have been arranged in tables which are practically self-explanatory.

Nineteen colleges, or 29.7 per cent, have a special department for teaching tuberculosis. This situation is usually found because some clinician has developed an unusual interest in tuberculosis. Obviously the intensification of this interest has resulted in improved facilities for teaching.

Thirty-three colleges, or 51.6 per cent, have availed themselves of the specialistic knowledge in teaching tuberculosis to their students. This is an important consideration. Nine additional colleges, or 14.1 per cent of the total, have teaching in tuberculosis divided between the internist and a tuberculosis specialist.

Teaching of clinical tuberculosis is done in general medical dispensaries in 71.9 per cent and in general hospitals in 68.8 per cent of the group referred to in table 4. These services are dependent on the occasional tuberculous patient admitted to them.

The instructor for teaching tuberculosis should be a member of the faculty of the college which is affiliated with the tuberculosis institution in an attending or consulting capacity.

Table 6 shows teaching affiliations with tuberculosis institutions. The colleges with special tuberculosis departments show affiliations in greater number than those having no special department. Affiliations are of importance only when the sanatoriums and those teaching are utilized to the fullest extent.

The college faculty having representatives on the specialty services of tuberculosis sanatoriums number only thirty-seven, or 57.8 per cent. This specialty type of affiliation is recognized today as important in rounding out not only the medical service to the patient but the medical knowledge given to the student.

Table 4.—*Type of Place in Which Clinical Work is Done*

Type of Place	Number of Colleges	Percentage of Colleges Reporting
General medical dispensaries	46	71.9
Special tuberculosis dispensaries	25	39.1
Tuberculosis sanatoriums.	28	43.8
Tuberculosis hospitals.	23	35.9
General hospitals	44	68.8

Eleven colleges reported resident clerkship affiliations of varying lengths of time. In our opinion, the resident clerkship plan is a most valuable asset to the medical students' tuberculosis curriculum.

This table shows that only nine of the sixty-four medical colleges offer regular postgraduate courses. There is a definite lack of facilities for postgraduate instruction for that large group of medical practitioners about to graduate or for those who have been in practice for many years. The colleges with special tuberculosis departments, numbering nineteen, have failed to appreciate this great need, for only one of this number offers a postgraduate course. The curriculum committees of a number of colleges complain of the difficulty in arranging their schedule to include more hospitals for special courses. This cannot hold true of the postgraduate course, which, when properly presented, attracts large numbers of physicians.

Table 5.—*Type of Instructor Giving Clinical Instruction*

Type of Instructor	Number	Per Cent

THE TEACHING OF TUBERCULOSIS IN EUROPE

The undergraduate teaching of tuberculosis in German universities has not been stressed to any considerable extent. Prof. Wilhelm His[1] of Berlin recently reported on such teaching in his country. A chair of tuberculosis does not exist in any German university.

---

[1] His, Wilhelm: Teaching of Tuberculosis, Tr. Internat. Union Tuberculosis, Oslo 7: 454-469, 1931.

Tuberculosis is discussed in the different divisions in lessons on pathology, anatomy, clinical medicine, surgery, pediatrics and dermatology. The roentgen interpretation is demonstrated in courses on clinical medicine. The lectures on tuberculosis, given in the universities, do not take place at regular intervals. They also are usually limited to pulmonary and surgical tuberculosis and the therapeutic methods that have been developed in the care of these conditions. Demonstrations on the diagnosis and treatment are included in the teaching curriculum, in outpatient departments and in the wards. The lectures on public health include discussions on the social aspects of tuberculosis. A great number of the universities arrange medical trips once or twice a year to visit sanatoriums and inspect their work. Tuberculosis dispensaries and sanatoriums are, however, not definitely affiliated for teaching purposes with the medical departments of the universities. In other countries on the continent of Europe a similar condition exists for teaching undergraduate students tuberculosis —tuberculosis not being taught in a special division but being given as part of the general courses in the curriculum. Sir Robert Philips of Edinburgh has manifested a deep interest in the teaching of tuberculosis. This has resulted in the development of a special department of tuberculosis at the Edinburgh University. A rounded out curriculum covers the various phases of this disease. The didactic lectures are amplified by practical demonstrations. This eminent authority on tuberculosis states that "the need for training in tuberculosis in one shape or another is generally felt."

POSTGRADUATE TEACHING OF TUBERCULOSIS IN EUROPE

Postgraduate teaching of tuberculosis in Germany was stressed long before it was in other countries and a good organization was developed for instruction to the medical practitioner. Professor His, in discussing this phase of teaching, brings forth the fact that all the universities organize re[illegible] courses for doctors, which include [illegible] are, however, a few universities which have organized special courses in this disease. The Central German Committee for Postgraduate Teaching organizes courses for the study of tuberculosis independent of those conducted in the universities. The teaching in some of these is done in sanatoriums or in the tuberculosis services of general hospitals. The curriculums are arranged so that they deal principally with problems of tuberculosis as they relate to anatomic pathology, diagnosis, therapeutics and social prophylaxis. Modified series of lectures are sometimes organized for Saturday and Sunday to appeal to medical practitioners who can attend without interrupting their work only on these days. From 1920 until 1929 the German Postgraduate Committee had organized 117 courses, with series of lectures in fifty-eight towns or sanatorial centers. The number of those in attendance has varied between 40 to over 200. Moreover, in Prussia, thirty courses were organized in thirteen sanatoriums, while in other German states ten sanatoriums functioned in giving twenty-three courses. In Italy, Holland, Norway, Austria, Poland, Rumania and Sweden, postgraduate courses are given with regular and irregular frequency. The limited number of such courses given in these countries fails to emphasize the importance of the tuberculosis problem. In some of these countries postgraduate teaching is subsidized and arranged for either by the government or by the public health agencies in connection with universities and tuberculosis institutions. Great Britain does not manifest the interest in postgraduate teaching that is in evidence on the continent.

A PROGRAM OF TUBERCULOSIS TEACHING

Medical colleges, located as they are in urban centers, have within a short distance sanatoriums for the care of the tuberculous. The sanatorium constitutes an ideal school for the study of tuberculosis. It requires only the association of the teaching faculty of the medical college with the sanatorium through the appointment of such teachers to the attending and consulting staffs.

TABLE 9.—*Postgraduate Instruction in Tuberculosis According to Status of Tuberculosis Teaching*

The staff specialists, recruited from the medical colleges, bring to the tuberculosis institution a knowledge not only of tuberculous conditions but also of nontuberculous complications that often require urgent care. The institution makes available, for purposes of lecture and demonstration, unlimited material. Realizing this, one of us,[2] in 1927, as director of the municipal tuberculosis organization of Chicago, organized a school of tuberculosis. A consulting staff, representing the professional ranks in the various specialties from the four class A medical schools in Chicago, was appointed. The courses were as follows:

A. *Undergraduate Teaching.* — 1. Resident clerkship. Twelve students were domiciled at the sanatorium for a period of from one week to one month, each student being assigned to one resident physician. A definite curriculum was outlined and followed.

2. Undergraduate didactic lectures. An entire class not in residence at the sanatorium was given a series of twelve half-day lectures there. These lectures involved the different phases of tuberculosis and practical demonstrations with material from the laboratories and infirmaries.

3. Undergraduate research fellowships. From six to eight students were assigned to assist in research problems during their vacation intervals of four months. This was to train and stimulate these men for future medical research. They were paid a small stipend and furnished maintenance.

B. *Postgraduate Teaching.* — 1. Graduate fellowships. A graduate resident fellowship in surgery and in medicine with remuneration and maintenance was appointed to each of these services. This was to train and prepare these fellows for special work, such as chest surgery. These fellowships were registered with the graduate school of one of the universities for a higher academic degree.

2. Postgraduate clinical instruction to the practicing physician in the environs of his own community. A group of physicians was consolidated into a unit through its local medical society. A meeting hall was obtained nearby. A series of didactic lectures was given by specialists in the various phases of tuberculosis, such as bacteriology, pathology, symptoms, diagnosis and x-rays. These lectures were profusely illustrated with material brought from the sanatorium laboratories. This was followed by three months of intensive chest diagnostic work in the local clinics of the sanatorium, maintained in various parts of the city. On completion of this course, if proficiency was demonstrated, an appropriate certificate was awarded.

Postgraduate special courses also were arranged for the practicing physicians at the sanatorium. The public health phases of tuberculosis work were emphasized.

During the four years of this program, approximately 1,000 senior medical students were given resident clerkships. Approximately 500 students also had the undergraduate twelve weeks' course of lectures in tuberculosis; 110 doctors were given postgraduate courses, and six resident undergraduate fellowships and two graduate fellowships were maintained.

CONCLUSIONS

Tuberculosis continues as one of the major problems from medical and lay standpoints.

The inadequacy of undergraduate and graduate instruction in tuberculosis in the medical colleges of this country prompted this report. This is evidenced by statistics which can be promptly analyzed.

Some medical colleges have thus far no provision for affiliation with tuberculosis sanatoriums so that their students can be properly educated in the problems of tuberculosis.

The European method places its main emphasis on postgraduate study. In contradistinction, a plan developed in this country stresses the undergraduate as well as the postgraduate instruction.

Special attention is directed to undergraduate teaching through the resident clerkship. Postgraduate teaching involves a systematic program of fellowships. Extension courses have brought to the community doctor the teaching clinic, making it possible for him to become familiar with the advances in the recognition and management of tuberculosis.

CURRENT CRITICISMS OF PSYCHIATRY

SANGER BROWN II, M.D.
ALBANY, N. Y.

This paper refers to fourteen articles containing criticisms of mental hygiene and psychiatry, which have appeared in magazines or medical journals during the past four years. They have been written by physicians, welfare workers, journalists and others, and have appeared in such publications as The Journal of the American Medical Association, *Journal of Nervous and Mental Disease, American Journal of Diseases of Children, Lancet, New York State Medical Journal* and *Outlook and Independent,* and in editorial pages of the New York *Times* and in the New York *World Telegram.* They have been printed under such titles as "The Menace of Psychiatry," "The Legend of the Prevention of Mental Diseases," "Psychiatric Bunk," "Psychiatry, the Weak Sister of Medicine" and "We've Gone Psychiatric."

The criticisms are chiefly unfavorable, although some are otherwise. While it is generally wise to ignore adverse comments, the object here is to try to clarify certain facts rather than to bolster up one side of an argument. The criticisms do not relate to the care of mental patients in institutions, but to what psychiatrists have been attempting to do in recent years in the community by way of early treatment, prevention of mental breakdowns, child guidance and so forth.

A pediatrician, under the title of "The Menace of Psychiatry," [1] criticized intelligence tests, behaviorism, psychoanalysis and particularly the educational campaign in child guidance. He took exception to remarks in Watson's book on behaviorism as follows: "No one today knows enough to raise a child. The world would be considerably better off if we were to stop having children for twenty years and were then to start again with enough facts to do the job with some degree of skill and accuracy."

In criticizing intelligence tests, he told of one young mother who was much disappointed because her child had an intelligence quotient of only 119 whereas a neighbor's child had a rating of 129! No explanation by the physician that the test was not an absolute criterion could shake her convictions of the significance of its literal interpretation. Again, this writer described a school in which intelligence quotients were posted and all the children knew their ratings: superior, inferior and so on. One child who was retarded had been placed in a class with morons, much to his and his parents' distress. The writer stated, in effect, that

---

Read before the Section on Nervous and Mental Diseases at the Eighty-Third Annual Session of the American Medical Association, New Orleans, May 12, 1932.

[1] Brennemann, Joseph: The Menace of Psychiatry, Am. J. Dis. Child. 42: 376 (Aug.) 1931.

mentality can be judged better through observation of the child by an experienced physician than by formal tests.

This critic believed that harm may be done by telling parents too much about child guidance. He stated that anorexia in children is indirectly traceable in many cases to the use of height and weight tables. This standardization encourages parents to keep charts and urge their children to eat more in case of underweight. He pointed out that children are like other young animals with normally hearty appetites, but because of this urging, often become disgusted with food. Hence a problem is created. He feared that this same attempt at standardization carried into the field of conduct and behavior will work even greater havoc.

Again, he questioned current methods in sex education and also the freudian interpretation of explaining some childhood conduct on the basis of the Oedipus complex, the infantile libido, etc.

Although this writer quoted the definition of psychiatry from Webster's Dictionary, he nevertheless included under psychiatry not only subjects legitimately belonging thereto, such as mental hygiene and child guidance, but also psychology, behaviorism and parental education. The latter subjects, while bearing on psychiatry, are related to it only in some respects.

As a contrast to this criticism may be quoted the remarks of another pediatrician,[2] as follows:

> Every pediatrician admits that his practice cannot be carried on effectively unless he faces and solves problems involving child guidance and parental education. He may dislike the idea that this attitude involves him in psychology, psychiatry and education, but he can hardly avoid the entanglements. . . .
>
> Several obvious attitudes are possible for him. The most comfortable one is to sit back and reflect upon the traditional prestige of the practioner of medicine. . . .
>
> A second relatively simple solution, widely practised, is to damn the whole notion of psychiatry, psychology, progressive education and the like and deny the validity of all criticism of our own upbringing. Reaction of this sort is extremely work of any kind. . . .
>
> A third possibility, which involves some difficulty for those who choose to investigate it, is based on a recognition by pediatricians that there must be something in psychology, psychiatry, and mental hygiene.

A director of an important social agency wrote a criticism of psychiatry under the title of "Psychiatric Bunk."[3] In this article, he criticized behaviorism and its theories, especially as to the methods of conducting experiments. He criticized those whom he terms as "half-baked, self-styled" psychiatrists who wish to psychoanalyze every one. He discussed so-called expert psychiatrists in the court room whose hair-splitting contentions mean nothing to the ordinary person. The article contained a criticism of intelligence tests as used in child guidance clinics, in examining immigrant applicants for admission to this country and in the army during the World War.

This writer further stated how a social worker investigating a child's home in a tenement district came to the obvious conclusion, after some weeks' study, that the child was living in a bad environment.

By this writer, a distinction was implied between the leaders of psychiatry and those whom he termed "half-baked," but in the paper the distinction is not very evident. He really seemed to regard them all as half-baked! Again, while he stated that there is a definite difference between psychologists and psychiatrists, he made no clear distinction in his article, and he seemed to prejudice his readers against psychiatry by his title "Psychiatric Bunk." Quotations from this article appeared in a number of papers.

A neurologist, under the title of "The Legend of the Prevention of Mental Disease,"[4] took exception to the educational campaign in mental hygiene. He stated: "Enthusiastic mental hygiene tells us that it is concerned with the prevention of mental deficiency, criminality, the psychoneuroses, the psychoses, antisocial traits, family unhappiness, divorce, prostitution, alcoholism, sexual perversion, epilepsy and other such simple matters. All one can do is to gape and wonder or, perhaps, ask a few questions." In the course of his discussion, the writer stated that criminality depends on inherited factors to a very large degree. He further asked what advance has been made in psychiatry in the past twenty-five years by way of new discoveries which will warrant promises that mental disease can be prevented.

The same writer spoke of what he called the shameful spectacle in the propaganda for cancer prevention, pointing out that while we employ the knife, radium and x-rays, nothing is known of true prevention or control of cancer. He feared for the results of a similar campaign in the field of mental hygiene.

Another neurologist was quoted as saying that psychiatrists are barking up the wrong tree in basing their theories on environment rather than on heredity. Further remarks attributed to him indicated that he was not in favor of a preventive campaign in respect to mental disease.

An En[illegible] when attending the International ([illegible] Hygiene held in Washington in May, 1930, visited a number of institutions and other psychiatric centers in this country at that time. He stated, under the title "Impressions of American Psychiatry,"[5] that in the United States one could see almost everything which was worst and also best in psychiatric practice. He commented favorably on the research activities in the leading psychiatric centers. One cannot rightly take exception to certain unfavorable observations made by him.

The foregoing criticisms fall into two main classes. In the one are activities which, although more or less identified with the mental hygiene movement, are not controlled by psychiatrists or exclusively of psychiatric nature. In this class belong intelligence tests, behaviorism and, to some extent, psychoanalysis.

INTELLIGENCE TESTS

Intelligence tests have been subject to more or less criticism since they first began to be used in this country in about 1912. It has been stated that intelligence cannot be measured, that emotions influence the result, that the tests may be studied up or that they may be deliberately faked.

Intelligence tests are used quite generally by psychologists in examining children, although psychiatrists also use them in child guidance clinics, schools for defectives and elsewhere. However, psychiatrists endorse intelligence tests only as they evaluate them along with the history, physical examination and other considerations. They have been loud in their disapproval of their unwise application. The psychiatrist in using intelligence tests may be compared to the pediatrician prescribing commercial infant foods on occasion. The latter would not wish to be held responsible for the use of these foods unless under his strict supervision.

[5] Macpother, Edward: Impressions of American Psychiatry, Lancet 1: 848 (April 19) 1930.

Despite drawbacks and limitations, intelligence tests are as accurate as many other scientific methods now in use. They no longer are regarded as infallible as their enthusiastic supporters once believed; nor do they carry with them the power of prophecy. If given and interpreted by those qualified to use them, they should not constitute a menace.

BEHAVIORISM

Behaviorism is a theory identified by some persons with the mental hygiene movement. However, any one criticizing psychiatrists should be better informed than to classify behaviorism as of psychiatric origin. The originator of behaviorism is not a physician, much less a psychiatrist. He probably would not feel flattered to have behaviorism, which has created world wide interest, regarded as a part of mental hygiene. A majority of psychiatrists understand behaviorism no more fully than do most other physicians.

PSYCHOANALYSIS

Psychoanalysis, since the beginning of the present century, has aroused interest in many parts of the world. However, while psychoanalysis has been closely associated with psychiatry, its theories did not originate from conventional psychiatric sources. Freud has never been closely associated with psychiatrists as a group. And psychiatrists, far from having endorsed psychoanalysis without reservation, have often been severe in their criticism of it. However, psychiatrists are investigating its principles, many of which have been incorporated in psychiatric practice without appreciation of the origin. Such terms as repression, retardation, inferiority complexes and many other terms used by psychiatrists are of psychoanalytic origin.

Psychiatry and mental hygiene have a broader field than psychoanalysis. It would be unfortunate if psychiatry limited itself to preoccupation with psychoanalytic principles and ignored the broad foundations on which it originated. For the present, it would appear best for those who are not fully conversant with psychoanalysis to refrain from undue criticism, but likewise to withhold their full endorsement.

Other activities of psychiatrists have been adversely criticized in the aforementioned articles. The latter group of activities are of strictly psychiatric origin, and psychiatrists are responsible for them. These include such activities as child guidance, public education in mental hygiene, the psychiatric social worker and expert court testimony by psychiatrists.

CHILD GUIDANCE

The education of parents in some aspects of the guidance of children has doubtless resulted in making some mothers unduly concerned about their children's development. As pointed out in one of the aforementioned criticisms, public education about medical matters may have an undesirable influence on some persons. Physicians are visited repeatedly by persons with normal hearts, requesting an examination, although they may have had many previous examinations. Reassurance is of little value to these patients as they are in constant fear that they will drop dead of heart disease. Others fear tuberculosis and seek frequent examinations, and still others fear cancer. There are patients who specialize in having operations and who succeed through persistent complaints in getting surgeons to operate on them, often more than once. Then there are some who do not fear disease for themselves but for their children.

These patients are seen both in private practice and in free clinics. A knowledge of disease has offered them a peg on which to hang their anxieties and complaints. While information about mental hygiene or preventive medicine gives such patients some definite disease to fear, it does not create the fear. The fear is a symptom of their nervous state. This situation, therefore, does not justify the suppression of public health movements.

Education of the public in the field of child guidance deals with such subjects as the training of young children in proper habits of eating and sleeping and in toilet habits, the acquiring of emotional control in early childhood, encouraging parents neither to pamper their children nor to dominate them, and the recognition of unfavorable teaching methods for some children who are scholastically handicapped. Any teaching which calls for too much standardization, as in height and weight or in mental qualities, is undesirable, as has already been stated. But such rigid teaching need not be a part of public education. Child guidance clinics are being used with increasing frequency in schools, in children's courts and by welfare agencies, and, wisely directed, they should be a benefit rather than a menace.

Some extremists, it is true, such as those advocating absolute liberty for the child under all circumstances and those cataloguing almost his every word and action, have unwisely attempted to take a part in child guidance activities. Psychiatry cannot control these misdirected activities any more than medicine can control faddists in the direction of nature cure, diets and other eccentric health activities.

The writer who referred to the needless investigation by the psychiatric social worker, as mentioned, was not fully justified in his criticism. A boy may live in poverty in a basement, but nevertheless grow up to be a successful and capable man. The social worker was doubtless looking for less obvious influences, such as an unfavorable example by the father or mother, insufficient oversight, bad companionship and so on. While social workers are doubtless prone to make mistakes, they will eventually fill the same place in the mental hygiene field as the public health nurse fills today in preventive medicine. Physicians are critical of the work of nurses at times, but this does not discredit the entire nursing profession, nor do some mistakes in social work discredit all social workers.

COURT TESTIMONY

Psychiatric testimony in the court room has been the subject of much criticism. This section of the American Medical Association and a special committee of the American Psychiatric Association have made careful studies and recommendations in the past regarding court testimony. Until these recommendations are seriously considered in court proceedings, little change is to be expected. However, psychiatrists are not the sole offenders in respect to expert testimony. Neurologists are likewise to blame, and other physicians who are not qualified by training to pass as experts not infrequently give so-called expert testimony. It is agreed by those best informed on the subject that no improvement may be expected as the law stands at the present in most states in respect to expert testimony.

When the time comes that the state, through the court, appoints a committee composed of psychiatrists selected from a list who have proper qualifications, more satisfactory results may be expected.

In one article, psychiatric court testimony is referred to as "jargon." It was pointed out by a journalist writing to the New York *Times*,[6] in defense of psychiatry, that psychiatric terms are not always comprehensible to the layman any more than are the terms of the biologist, the chemist and the surgeon. This fact should not justify the use of the term "jargon" in this connection.

In what light are the foregoing criticisms to be regarded? While those mentioned come from a small number of persons, they no doubt voice the feelings of many more. The titles cited, in which psychiatry is spoken of as bunk, a menace, a legend and a weak sister, suggest bias on the part of these writers, to say the least; but I shall pass over that aspect of the matter. To some extent, these criticisms undoubtedly represent opposition which commonly exists toward unfamiliar teachings. Public education is often an effort to make people do something to which they are either indifferent or opposed. Forcing people to wash milk bottles, remove garbage, etc., makes the public health movement unpopular with some persons; likewise, insistence that the patient discuss unpleasant facts or admit wrong points of view makes mental hygiene unpopular in some quarters. Again, over-enthusiastic promoters who make extravagant claims often make opponents rather than converts to their cause.

Some of the criticisms outlined are based on the common but mistaken belief that mental disease is always inherited and the expression of a latent mental weakness or instability. This point of view implies that insanity is one disease and brought on by one cause. As a matter of fact, there are many mental diseases variously divided into groups the same as are physical diseases. For purposes of classification, mental diseases are often divided into two main classes: those of organic origin and those for which no organic cause can be found.

Organic conditions, i. e., such as syphilis, acute infectious disease, traumatic brain injuries and arteriosclerosis, and toxic agencies, including alcohol, drugs, etc., exist as causes in slightly over 50 per cent of all cases admitted for the first time to institutions for mental disease. In view of the fact that such well known organic causes are known should not prevention be attempted?

In respect to nonorganic causes, inherent factors are, of course, important, but an inherent tendency toward disease does not imply that its occurrence is inevitable. Those constitutionally predisposed toward tuberculosis have not stood in the way of a tremendous reduction in the death rate from that disease in the past forty years. In mental disease, such factors as an unfavorable environment in early childhood, prolonged mental conflicts, undue repression of emotions and other mental causes may either lead directly to a mental breakdown or prepare the soil for mental disease at a later date.

Again, there are social influences which are harmful to mental health. Such influences as the repressive atmosphere once existing in New England, the refusal to admit mental conflicts or discuss them with any one, the bitter condemnation of minor wrongdoings in oneself or others, or again the complete freedom from restraint as advocated by some after the World War, these trends in society are not conducive to mental life.

Will not mankind be benefited if these unfavorable influences either in the life of the individual or in society are corrected as far as possible through public education by recognized mental hygiene societies rather than permitted to go unchallenged by any authoritative body?

Mental hygiene has attracted much attention to itself in recent years because of the increasing interest of many persons in the functioning of the mind. A discussion of mental mechanisms, an interest in self-analysis or in analyzing other persons, in investigating the working of the mind and in evaluating emotions has taken place in the daily press, in public addresses and elsewhere. Biologists, psychologists, historians and educators, as well as journalists, novelists and public speakers, have expressed themselves on the subject of mental functions. It would be misleading to think that psychiatrists and mental hygienists were the sole originators of this movement as some critics seem to believe. Psychiatry has been known to a mere handful of people until quite recently.

The present age has brought with it complications in society which have resulted in conflicts affecting both classes and individuals. Where these conflicts seem to be of mental origin, they should be investigated and studied just as the causes of physical disease are studied. This point of view has doubtless increased the public's interest in mental hygiene. In taking up this question of mental health, psychiatry is merely paralleling what general medicine has done in public health.

If this movement is not led by responsible leaders, the field will be left open to faddists and fanatics who foist their theories on the public the same as quacks have succeeded in doing at times in the treatment of physical diseases. A moratorium in mental hygiene, as suggested by one of the aforementioned writers, would leave the field open to a group of charlatans.

Books on mental health written by nonmedical persons have a wide circulation. Some titles are as follows: "The Mind in Action," "Lives in the Making," "Use Your Mind," "Straight and Crooked Thinking," "The Jungle of the Mind," "An Alphabet of Attributes" and "Children and Their Parents." Much of the material of these books has been gathered from responsible sources in the mental health field. Books by extremists and faddists purporting to be on mental health would doubtless be much more numerous than they are now if there were no mental hygiene teachings to offset them.

If universal harmony existed in the world today, a mental health program would be superfluous. But more than a fair share of the ills of the world arise from circumstances which might be avoided through fuller understanding by man of his own psychology and mental outlook. Society suffers from mental as well as from physical ills. Some day it may be possible to recognize these unhealthy mental trends more clearly than now.

In the meantime, concrete evidences of lack of satisfactory mental poise on the part of a considerable percentage of the population is seen not only in frank mental disease, but in the neuroses, the psychoneuroses, emotional instability, delinquency, crime, problems in children, maladjustments between married persons and other evidences of lack of sound mental health in various forms. With these conditions so prevalent, the need of education in the field of mental health should be evident. In fact, the advantages of teaching mental health as a part of all education may be appreciated in the future. Members of the medical profession and others interested in social welfare will render an important service if they not only refrain from ill considered criticism of the mental hygiene movement, but lend their support to recognized mental agencies.

[6] Barnes, H. E., in Liberal Viewpoint column, New York World-Telegram, Dec. 5, 1931.

ABSTRACT OF DISCUSSION

Dr. H. Douglas Singer, Chicago: I think that one can get somewhat unduly alarmed by the facts of criticism. It seems to me that criticism is a healthy sign. It means at least that something is stirring. I wonder whether the criticisms that were offered in the address by the chairman do not follow similar lines. Investigations in medical schools point out the lack of properly trained personnel even in the field of psychiatry itself. If one adds that the whole subject has been, as Dr. Brown said, a sort of foreign body, isolated as Dr. Ebaugh said, one can readily understand the reason for these recurring criticisms. I think that the answer is that those who are interested in this field should do some real work rather than writing quite as much as they tend to do. If psychiatry is taught as it should be taught in every medical school there will be no more of this type of criticism.

Dr. George W. Hall, Chicago: I was pleased to note the broad view that the author took in the presentation of his subject. One must expect criticism in whatever field one may be working in, especially if the views one expresses are in advance of those to which the public are accustomed. That should not be discouraging, however. The subject of mental hygiene, as has been the case with many other topics of medicine, necessarily must undergo the acid test before it is recognized as one of the essential topics that have to do with the dealing of the mental side of patients. There is no question, however, about the foundation on which it is placed, and the future development will eventually present itself in a more crystallized form. I think that if the author's views could be followed out in the way in which he has outlined, by accepting the experience of the psychiatrist and the neurologist rather than placing it primarily in the hands of individuals who have not had medical training, it will reap more definite results than by training individuals to be psychoanalysts who have not had sufficient experience in the basic elements of neurology and psychiatry.

Dr. George Stevenson, New York: In the past week criticisms have come to me in two different cities. They were particularly concerned with the relations between pediatrics and psychiatry, and particularly pediatrics and child guidance. From this criticism it is evident that these issues are straw men that have been set up by some one poorly acquainted with what is going on. In other words, in my contacts with people in the child guidance field the general point of view is that the psychiatrist in child guidance should be handling the more complex problem children, and that the pediatrician and the general practitioner, who sees the child in all his health relationships, should be the first line of defense. That, I think is the prevalent point of view of psychiatrists in child guidance work, but it is also their point of view that pediatricians and general practitioners should be trained to carry that responsibility which they cannot escape. The essential point I want to bring out is that there have been straw men set up creating an issue between pediatrics and child guidance or psychiatry, and between general medicine and psychiatry, whereas there is no real issue between the leaders in those two fields. The apparent issue, if it is studied, grows out of the gropings and defenses of those who are not in contact with one another. One finds exactly the same thing in the relationship between child guidance and public schools. In response to a point brought out in the discussion, I should say that it is far more dangerous to assume to prepare young physicians and young nurses to deal with patients and train them to deal with only organs than it is to prepare the certain special group referred to go into the home in order to make an objective study of it and to carry treatment into that situation. One of the examples of criticism which Dr. Brown brought up is particularly interesting if it is looked at as a psychiatric problem. Here is the director of a social agency. He has created this agency and is the founder of his movement. In founding the movement, as is the case with many founders, he thought it would be a cure-all, a thing that would deal with the delinquent boy, the maladjusted boy, a thing that was entirely sufficient in itself. But this doesn't turn out to be the case. This child guidance clinic comes along and attempts to add to what he has done. It recognizes the value of the job he has done. It recognizes its defects and attempts to deal with them, but this individual is dissatisfied because his baby is defective and he must make it appear to be absolutely whole by pronouncing the lack of necessity of this other child guidance procedure.

Dr. Sanger Brown II, Albany, N. Y.: In the next twenty years, society will do much toward the prevention of mental disease. There has been wide interest in the early treatment of mental disease and there will be full developments of this movement in the future. There need be no fear from the criticisms that have been cited, if this movement is kept under the general direction of the medical profession. Mental hygiene teachings are being attempted in universities, colleges and elsewhere, but unless these teachings are guided by physicians and others familiar with mental hygiene, mistakes are liable to result.

A BIOLOGIC CONCEPT OF DISEASE

ELI MOSCHCOWITZ, M.D.
NEW YORK

The more one sees of chronic disease the more keenly one appreciates that what has been observed are not sharply defined genera but transitions of morbid states from one to another. One realizes that much of the differentiation that has resulted from more refined observation and more detailed laboratory investigation has tended to confuse rather than to simplify the issue and has caused the classification of disease to be more artificial than biologic. Too often diseases are classified according to a mere grouping of signs and symptoms, rather than in relation to a precise etiology or a well observed consistent pathogenesis. Many chronic diseases, like biologic species, present an evolution from the primitive or embryonic to a full-fledged form. It would be just as consistent to classify the earliest, the intermediate and the final phases of disease as separate entities as it would be to classify the tadpole and the frog as different species.

Most of the confusion in classifying disease comes from an ignorance of the causes of disease. As long as the cause of many chronic maladies is unknown, so long will one be forced to classify disease on the basis of clinical differentials. This does not mean, however, that mere modifications of disease processes require separate classification. Time and again conditions that are regarded as separate disease entities eventually prove to be only biologic sports or mutations.

It is not generally realized that those whose entire medical experience centers in hospitals and consultation work see only a small cross section, usually the terminal one of the disease. Of the previous life cycle of the disorder they are ignorant; at best the previous cycle may sometimes be painfully reconstructed. To be able to follow a malady from the beginning to the end is the special privilege of the practitioner, and the problem of unraveling the evolution of morbid processes is his. MacKenzie recognized this a decade or more ago, and the institute in St. Andrews, in which the very begin-

---

Read before the Greater Boston Medical Society, Boston, March 1, 1932.

nings of disease are studied, is the outcome of his reflections.

In the absence of a knowledge of etiology, one of the best bases for the classification of chronic disease is a uniform and consistent pathogenesis. One may even be unaware of the precise progress of events, of a correct teleologic interpretation, but one is safe in saying that maladies that have the same pathogenesis are usually intimately related. At the outset, therefore, diseases may be classified into two great divisions. Those which have a well established pathogenesis possess the dignity of a distinct genus or disease; those which have been classified on the basis of a mere grouping of clinical phenomena are syndromes.

This question of evolution of morbid states is not merely a matter of correct interpretation. Current statistics on nosology lose much of their entire significance, or even all of it, because the recording clinician did not note in what phase of the process the symptom or sign occurred. It is like trying to correlate a number of unrelated variables.

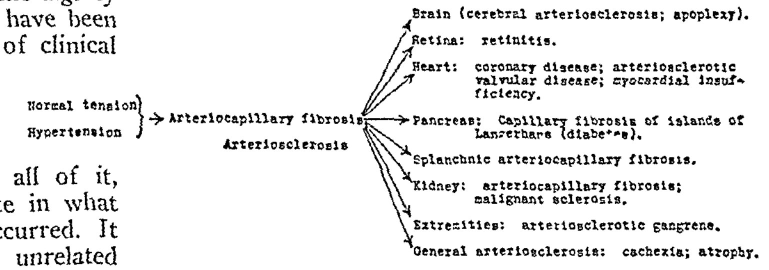
Studies in this direction will tend not to split up disease complexes, as was so commonly done in the past, but to unify them. In order to show how a biologic approach to the study of classification should be made, I shall submit a number of rather common instances in which the evolution of pathologic conditions is exemplified.

FIVE INSTANCES EXEMPLIFYING THE EVOLUTION OF PATHOLOGIC CONDITIONS

1. *Hypertensive Disease.*—Most physicians can recall time honored teaching in which renal conditions "caused" hypertension: the large red kidney, the small red kidney, the large white kidney, the small and large granular kidneys and the contracted kidneys of different sizes and hues. These supposedly different species of renal disease associated with hypertension are now known to fall into two groups, each with its own distinct pathogenesis: arteriocapillary fibrosis and glomerulonephritides.

A. Arteriocapillary Fibrosis: It has become manifest that the arteriocapillary fibroses are not the cause but the results of the hypertension, and the supposedly different kinds of kidney represent phases of a pathogenesis in which the earliest is represented by a kidney with minimal vascular lesions and the final the small scarred, contracted kidney; only the latter is a final result. The entire pathogenesis is perfectly explainable on the basis of vascular damage, and the kidney found post mortem represents, therefore, only the localized expression of a generalized arteriosclerosis of the greater circulation. It must be remembered that the patient usually dies, not directly from the renal damage but from a vascular or circulatory crisis, and the state of the kidney depends on the period of the disease in which the crisis occurred. "Nephritis" and the arteriosclerosis have no mutual reactions on each other but are the simultaneous reactions to the same insult, namely, hypertension. In the evolution of hypertensive disease the renal disorder represents only a small part of the clinical picture, the brunt falling on such organs as are more profoundly affected by the arteriosclerotic change. Chart 1 summarizes all the possible eventualities.

Why the brunt of the disease should fall on one organ more than on the other is an intriguing problem, but this conception explains why various combinations of clinical manifestations are often possible with hypertensive disease. In other words, here are a great number of clinical products the embryonic stage of which is a pure functional derangement; namely, hypertension. It is only necessary to add, in order to avoid misinterpretation, that these final products are perfectly possible without hypertension. I have shown that arteriosclerosis is the result of the normal intravascular pressure and is due to no other factor; hypertension simply brings about the vascular changes earlier and in a more intensified degree than the normal involution.



Normal tension
Hypertension
Arteriocapillary fibrosis
Arteriosclerosis
Brain (cerebral arteriosclerosis; apoplexy).
Retina: retinitis.
Heart: coronary disease; arteriosclerotic valvular disease; myocardial insufficiency.
Pancreas: Capillary fibrosis of islands of Langerhans (diabetes).
Splanchnic arteriocapillary fibrosis.
Kidney: arteriocapillary fibrosis; malignant sclerosis.
Extremities: arteriosclerotic gangrene.
General arteriosclerosis: cachexia; atrophy.

Chart 1.—Eventualities possible in hypertension.

B. Glomerulonephritis: I[1] have called attention to the interesting natural history of glomerulonephritis. If patients with this disease are studied over a period of years, the following eventualities may occur:

(*a*) Complete clinical and anatomic recovery.

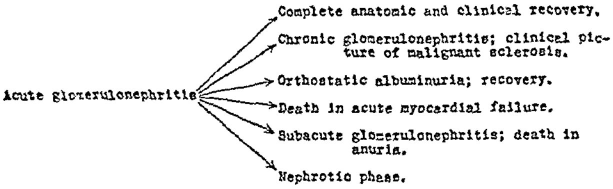
(*b*) Recovery from the acute phase; persistence of albuminuria for a period of a few months to many years; progression of lesion with recurrence of hypertension, arteriosclerosis, death in uremia or from myocardial failure with the clinical picture of malignant sclerosis.

(*c*) Recovery from acute phase; persistence of albuminuria, which is frequently orthostatic in type for many months; recovery.

(*d*) Acute glomerulonephritis; death in acute myocardial failure.

(*e*) Acute glomerulonephritis; persistence of excessive albuminuria resulting in a transition to the nephrotic phase; death from uremia or myocardial insufficiency.

I have not observed a complete clinical recovery with a recurrence many years later. As far as my experience is concerned there is either complete recovery or some evidence of clinical continuity. Without knowing what has gone before, it is sometimes impossible to determine, when the clinical picture of malignant sclerosis arises, whether the disease began as an essential hypertension or as a glomerulonephritis. The same problem arises in the interpretation of the origin of the nephrotic syndrome.



Acute glomerulonephritis
Complete anatomic and clinical recovery.
Chronic glomerulonephritis; clinical picture of malignant sclerosis.
Orthostatic albuminuria; recovery.
Death in acute myocardial failure.
Subacute glomerulonephritis; death in anuria.
Nephrotic phase.

Chart 2.—Eventualities possible in acute glomerulonephritis.

2. *Nephrosis.*— In a previous paper[2] I have discussed the validity of nephrosis as a definite disease concept and tried to show that it has no single etiology or definite background in pathology. In Mount Sinai

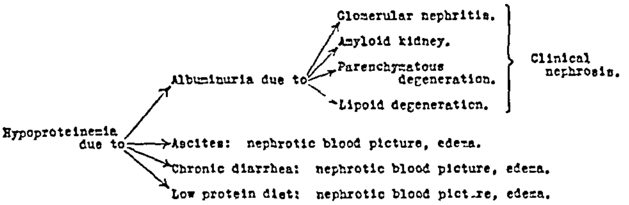
[1] Moschcowitz, Eli: New England J. Med. **202**: 320 (Oct.) 1930.
[2] Moschcowitz, Eli: Am. J. M. Sc. **172**: 469 (Oct.) 1926.

Hospital the clinical nephrotic picture as described by Epstein and others has been associated with four different lesions: lipoid degeneration, chronic parenchymatous nephritis, amyloid disease and subacute or chronic glomerulonephritis. In other words, nephrosis is not a disease but a syndrome with fairly well defined characters, the prominent evidences of which are fairly uniform blood chemistry and edema.



Glomerular nephritis.
Amyloid kidney.
Parenchymatous degeneration.
Lipoid degeneration.
Clinical nephrosis.
Albuminuria due to
Hypoproteinemia due to
Ascites: nephrotic blood picture, edema.
Chronic diarrhea: nephrotic blood picture, edema.
Low protein diet: nephrotic blood picture, edema.

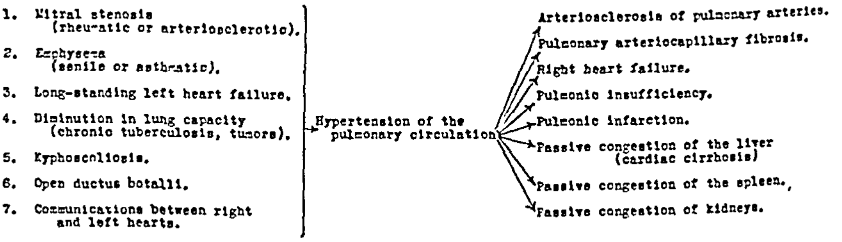
Chart 3.—Relations of nephrosis.

The hypothesis of Epstein,[3] who believed that the clinical manifestations of the disease were due to loss of protein, has been to a large extent confirmed by Leiter,[4] who proved that plasmapheresis in animals produced a clinical picture that simulated closely that of nephrosis in man. A nephrotic blood picture is also noted in loss of protein within the body itself, as in ascites. This is not the place to enter into the interpretation of the various clinical phenomena of nephrosis, as determined by the loss of protein, but it is pertinent to note that the edema, perhaps the most constant of all the evidences of nephrosis, is perfectly explainable on the principle of the law of Starling, who found that the exchange of fluid between the blood vessels and the tissues depended on a balance between the hydrostatic pressure within the capillaries and the osmotic colloid pressure of the plasma, which tend to neutralize each other, a law which Epstein brought into his conception. This is important for the explanation of the mystery of the edema noted on the continent during the war, where the diminution of protein was due to insufficient protein intake, and the edemas noted in the chronic diarrheas. The cause of a primary nephrosis, which Epstein described as "diabetes albuminuricus" and which often results in recovery under an appropriate diet, is still unknown. It is possible that the lipoid and parenchymatous renal lesions may be the result of an unknown primary disorder of metabolism. The amyloid kidney and the chronic glomerulonephritis are undoubtedly primary. Biologically speaking, therefore, nephrosis is only a syndrome and not a disease, and any discussion of the subject is well nigh valueless unless its origin is known.

3. *The Evolution of Hypertension of the Pulmonary Circuit.*—Hypertension of the pulmonary circuit leads to pathologic changes which are comparable in every detail to those consequent on hypertension in the greater circulation, the one large difference being that, owing to the blood supply, only two organs, the lungs and the heart, are directly affected, the other organs of the body being affected only secondarily. It is important to recognize that the two circulations are entirely independent as far as the incidence of the hypertension is concerned, and that the dominating lesion of hypertension of the pulmonary circuit is arteriosclerosis of the pulmonary arteries. The changes in the lung are comprised under the generic term arteriocapillary fibrosis, and the lesions are morphologically identical with those seen in the kidney in hypertension of the greater circulation. In other words, although the pressure cannot be measured in the pulmonary circuit, the presence of arteriosclerosis of the pulmonary vessels proves at once that a persistent hypertension of this circulation has been present. The cause of the pulmonary hypertension is always mechanical and in the order of frequency are the following: mitral disease, especially mitral stenosis, emphysema, long standing failure of the left heart, marked diminutions in pulmonary volume (e. g., chronic pulmonary tuberculosis) open ductus botalli, kyphoscoliosis, and communications between the right and left hearts. Schematically the evolution of hypertension of the pulmonary circuit may be represented as in chart 4.

It is evident that the evolution of the various fundamental diseases causing hypertension of the pulmonary circuit covers a broad range both clinically and pathologically. The life cycle is a long one and it is therefore highly important for clinical purposes to recognize in what stage of the evolution the disease process lies.

4. *Exophthalmic Goiter.*—This comprises a series of clinical disorders, the earliest of which have been represented under such various terms as autonomic unbalance, neurocirculatory asthenia and basedoid. The intermediate phases have been described under the generic heading of formes frustes, while the final phases, known conventionally as Graves' disease, with the quadrad of symptoms, tremor, enlarged thyroid gland, tachycardia, and increased basal metabolism, represent the fully developed clinical expression of the disease. Occasionally one has the privilege of observing these various phases passing into each other, both in a forward and in a backward direction, and the common denominator which brings unity to the clinical concept is a characteristic constitution, partly anatomic but mostly psychologic, which persists as a residue no matter what form of treatment is undertaken.



1. Mitral stenosis (rheumatic or arteriosclerotic).
2. Emphysema (senile or asthmatic).
3. Long-standing left heart failure.
4. Diminution in lung capacity (chronic tuberculosis, tumors).
5. Kyphoscoliosis.
6. Open ductus botalli.
7. Communications between right and left hearts.
Hypertension of the pulmonary circulation
Arteriosclerosis of pulmonary arteries.
Pulmonary arteriocapillary fibrosis.
Right heart failure.
Pulmonic insufficiency.
Pulmonic infarction.
Passive congestion of the liver (cardiac cirrhosis)
Passive congestion of the spleen.
Passive congestion of kidneys.

Chart 4.—Evolution of hypertension of the pulmonary circuit.

If the disease is not arrested, various eventualities may arise. First, the persistent tachycardia may lead to myocardial insufficiency. This may result in a number of ways; either directly through the persistence of the tachycardia, through the intermediary stage of an arrhythmia, usually auricular fibrillation or, finally, through the increase and persistence of the usual hypertension that is associated with the tachycardia of exophthalmic goiter. This hypertension in turn may bring about the changes in the greater circulation which have already been discussed. I have seen a number of such evolutions. All in all, the cardiac phase of persistent exophthalmic goiter may be so prominent clinically that the conventional evidences of the exophthalmic goiter appear submerged and it is only by careful reconstruction of the patient's previous course that the true origin of the cardiac phenomena may be determined. The second and, fortunately, less frequent eventuality is the transition to acute thyrotoxicosis and death. The scheme for the evolution in exophthalmic goiter may be represented as in chart 5.

[4] Leiter, Louis: Proc. Soc. Exper. Biol. & Med. 26: 173 (Nov.) 1928.

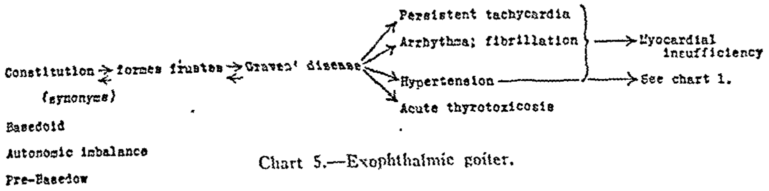

Chart 5.—Exophthalmic goiter.

5. *Toxic Hepatitis.*—This term covers disorders previously known under the names of catarrhal icterus and acute yellow atrophy. These maladies had always been regarded as separate diseases, the main difference being that in the first the patient recovered and in the second the patient died. Since, however, clinically indubitable cases of catarrhal icterus showed lesions of the liver closely resembling those of acute yellow atrophy[5] and, furthermore, since the clinical transition of undoubted catarrhal icterus into equally undoubted acute yellow atrophy is not infrequently seen, it is strongly probable that the two diseases are identical, varying only in intensity. The distinction between the two diseases is no longer a question of the survival of the patient, for it has become clear that patients even with what appears clinically to be acute yellow atrophy recover from the acute phases, the proof being that such patients who happen to come to autopsy reveal profound cirrhotic and compensatory changes that could have come only through a profound and diffuse destructive hepatic damage. Some observers, such as Eppinger, are willing to go so far as to say that the large group of diseases covered under the term splenomegalic biliary cirrhosis arises from a previous clinically severe toxic hepatitis; but as far as I am aware, nobody has yet observed this transition. In passing, the follow up of various forms of destructive liver disease over long periods is something greatly to be desired: physicians are still unaware of the early phases of such rare hepatic diseases as splenomegalic biliary cirrhosis, Banti's syndrome and Hanot's cirrhosis.

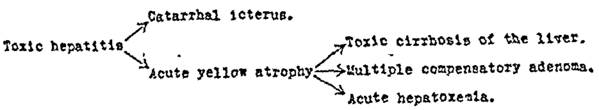

Chart 6.—Toxic hepatitis.

COMMENT

I have cited only a few evidences of the evolution of common diseases with which I happen to be somewhat familiar. There are many others, especially of the rarer varieties, that could be cited. For instance, all evidence points to the fact that diseases associated with a disturbance of the lipoid metabolism, such as amaurotic family idiocy, Niemann-Pick disease, Schüller's disease and the Christian syndrome, are closely related and may even be transmuted from one into the other. In blood diseases, the various forms of agranulocytosis are not sharply defined conditions but represent different reactions between the host and the infection. The aplastic anemias represent end products from exhaustion of the bone marrow due to a different previous disease of the blood-forming organs.

The important point in this brief summary is to call attention to the value of the biologic assay in evaluating disease and to the necessity for studying its evolution over more extensive periods than have hitherto been customary. Unfortunately, the number of diseases in which there are positive criteria or tests for diagnosis, such as the finding of the tubercle bacillus, are limited. For the others, until either a definite cause or a definite pathogenesis has been discovered, the only way to reach an understanding of the disease is by studying its evolution, both clinically and anatomically. Such a study, moreover, is necessary in order to determine the etiology of certain obscure conditions of a long life cycle. What, for instance, is the earliest phase of the leukemias? of pernicious anemia? of Gaucher's disease? of primary polycythemia? The determination of such origins may furnish an important clue to their causes.

THE CLINICAL TEACHING OF PREVENTIVE MEDICINE

DWIGHT O'HARA, M.D.
Professor of Preventive Medicine, Tufts College Medical School
BOSTON

The most groping field in the medical curriculum today is that in which we are trying to color the teaching of the practice of medicine with a preventive tinge. The attempt is being made in various ways in various places. Dr. Rosenau, at Harvard, has for several years been conducting amphitheater demonstrations in which the sick man may be made the beginning of a clinical discussion of the hygienic, epidemiologic and public health aspects of disease. Dr. Leathers, at Vanderbilt, has established a fine cooperation between the medical school and the state, county and city health departments, as well as between his own and the other departments of the school, in which the prevention of certain diseases is included in their pathologic and clinical presentations. So we find ourselves, each trying to use the available facilities toward the same end, but each being routed over a somewhat different road, with a different type of car and with by no means the same supplies of oil and gasoline. If here, at the crossroads, we can exchange a word or two descriptive of the scenery that we have been encountering, it may be helpful in deciding where the main and super highways should be built.

A plan which we are developing at Tufts College Medical School differs in some respects from other methods that have been devised. Since 1928, fourth year students have been engaged in the home care of patients under the supervision of graduate instructors in the district service of the Boston Dispensary. This service, the application of which to the teaching of medi-

---

Read before the Section on Preventive and Industrial Medicine and Public Health at the Eighty-Third Annual Session of the American Medical Association, New Orleans, May 13, 1932.

cine has been described by Dr. Joseph H. Pratt,[1] provides in a unique way the chance to point out preventive opportunities under the circumstances that confront the practicing physician. The student calls on sick people in their homes every day, and they, his own patients, are used as clinical material. During the past year, while on this service, each fourth year student has attended a series of sixteen conferences. These amplify Dr. Pratt's regular conferences on the practice of medicine and have been largely conducted by Dr. Samuel H. Proger. In them we have tried to do two things: first, to interest the student in the social aspects of disease, and second, to bring him into contact with suitable opportunities to institute preventive measures. The actual circumstances of a case in the district are assigned to be investigated and reported on, together with collateral reading assignments. The prevention or amelioration of an attack of measles, for example, may be discussed in terms of the exposure of a certain family, individual members of which may be known to be tuberculous or otherwise vulnerable. On an examination at the end of the district service each student is asked to discuss the preventive aspects of some particular case that he has seen during the preceding months.

In most of this work we are dealing with the problems of the individual, and concern ourselves with such things as the sanitary features of water, milk or food supplies only when they threaten the welfare of the individual. The environmental factors that favor various diseases and their treatment are analyzed, and an attempt is made to present the available community resources which support, in private practice, the necessary therapeutic or protective treatment. Not only the available resources of the large city but their counterparts in smaller communities are considered, down to the point of unorganized practical neighborliness, which seems to exist in inverse ratio to the population in the country. Thus the student is brought to see his future place in community life and the part that he, as a physician, may be expected to weave in the social fabric.

Tufts Medical School has a particular interest in the provincial problems of New England. We, therefore, consume little time with hookworm disease, malaria or tropical medicine. Smallpox, diphtheria and typhoid fever, on the other hand, are important diseases. While these three diseases are preventable and generally well controlled, they are a potential menace at all times, and we use them as the great examples of actual accomplishment. There is a frontier in preventive medicine, behind which the control of certain diseases is a matter of custom or statutory regulation. These three diseases fall into the group behind this frontier. In Massachusetts vaccination against smallpox is required of all public school children. School age has thus come to be the traditional age for vaccination, and practitioners' offices are filled with 4 year olds during the late summer and fall of every year. We can point out that vaccination between the ages of 2 and 6 months is simpler and safer and provides a larger measure of community protection than the present custom. This brings to the student's attention a large group of unvaccinated persons—a surprisingly large number when a student begins to count them on his daily rounds.

This is also the group of persons who are most susceptible to diphtheria. In Boston, for several years, the custom has been to make a mass appeal for diphtheria immunization to the parents of children in their first year of school. Last summer Dr. S. H. Rubin appealed to the doctors and the parents of the preschool children to have, among other things, their toxin-antitoxin or toxoid inoculations attended to before school opened. The next and last step will obviously be to urge diphtheria immunization for all children at the age of 6 months. It is easy for our students to see how they, the family doctors of the district, are the logical ones to take this step, and a few have actually fared forth on such missions, although it was not required of them. Had such a custom been prevalent in Massachusetts during the past decade, 2,381 cases of diphtheria and 130 deaths might have been averted in the year 1931. Here, then, are specific procedures that can be advocated.

SCARLET FEVER

We are next forced to take a stand of some sort on controversial subjects, the major one at the present time being the prevention of scarlet fever. Six years ago, when scarlet fever knocked at the door of preventable diseases, asking to be admitted on the basis of antitoxic immunity, we were inclined to accept her, provided she could hide her scarlet past. But even though scarlet fever may take off her rouge, change her name and never walk the streets again, closer acquaintance leads us to doubt the respectability of her associates, the hemolytic streptococci. In learning to cope with the toxin of the diphtheria bacillus, we conquered that disease. Not so, however, with the toxin of scarlet fever streptococci; one may immunize against it all one pleases, but the causative organism remains, a streptococcus just the same. In a personal observation of perhaps 500 cases of scarlet fever I have seen but 1 patient who died of primary toxemia. We are inclined to look on the prevention of the primary toxic manifestations of scarlet fever as a luxury, and to instruct our students not from the recent published material on the subject, but in terms of what they actually encounter in the district and will, of course, later encounter in practice.

There has been no difficulty this year in finding available material for such instruction. The following, for instance, is taken from a student's report to the conference, February 6, on a family of nine:

> Thursday, January 27, Patrick, aged 4 years, developed a sore throat and fever and vomited once. During that time he continued to play with his brothers and sisters. On the following day his mother noticed a generalized rash, and on the same day Joseph, aged 9, who had had scarlet fever before, developed a severe tonsillitis and pharyngitis, his throat appearing much like Patrick's. On Saturday, two days after the onset, Dr. Olef was called and diagnosed Patrick's case as one of scarlet fever, and Joseph's case as tonsillitis and pharyngitis. In the two day interval between Saturday and the preceding Thursday, those children who attended school continued to do so. On February 3, Rosemary, who had had scarlet fever, developed an acute follicular tonsillitis, pharyngitis and cervical adenitis, with a temperature of 101.4 F. (oral) but no rash.
>
> This family of nine people live in but four rooms, two of which are set aside as bedrooms and contain one double-sized bed each. One of the bedrooms is adjacent to the kitchen. The other is separated from the kitchen by the dining room, so called, in which there is also a couch. When there is no illness, Mr. and Mrs. King, Patrick (the patient with scarlet fever) and Timothy, the baby, sleep together. They were all sleeping together when Patrick became sick. Why Timothy, who is only 2 years old, has not shown scarlatinal manifestations is perplexing. (Timothy did contract scarlet

---

[1] Pratt, J. H.: New Features in Clinical Teaching, New England J. Med. **203:** 1 (July 3) 1930.

fever on February 7, the day after this report was made.) Joseph, with his tonsillitis, was sleeping with three other members of the family. Since Patrick and Joseph became ill, things are arranged differently. Mrs. King sleeps with Patrick in the bedroom farthest from the kitchen, and Mr. King has been sleeping with Joseph on the couch. The remaining five children slept in the other bed, Rosemary, who has since become ill, among them. When she became ill, I tried to persuade Mrs. King to isolate her from the other children. She promised to do so, but when visited on the following day, Rosemary still occupied the same place in the back bedroom. When asked about it, Mrs. King explained that the family was receiving aid from the welfare society in return for some work that her husband was doing, and that she could better afford to have the children sick than her husband.

Such a case illustrates that the challenge of scarlet fever is not that of its harmless rash, but the larger challenge of the hemolytic streptococci. While these have been classified under such terms as Streptococcus erysipelatis, Streptococcus scarlatinae and Streptococcus epidemicus, one is tempted to philosophize and compare them to groups of persons—musicians, for instance. Some are pianists; others are violinists; still others perform on the piccolo. There is a discipline in the concert hall of the laboratory, where one is apt to find each artist playing his own instrument, but at home in the cool of the evening the clinician will sometimes catch the piccolo player with a trombone—and booming out a very good tune with it, at that! For the fourth year student such circumstances as these constitute a glimpse behind the scenes of the modern contagious hospital and show him how relative the isolation of contagious diseases often is in the community.

TUBERCULOSIS

Tuberculosis is, of course, one of our great problems. Tuberculosis is a disease, the prevention of which is a matter of understanding and optimism. After calling on a patient and studying his environment one of our students reacted as follows, in summarizing his report:

> As institutional care has been refused and cooperation is impossible and not agreeable to the patient, there is dying on Decatur Street a 16 year old youth who has no right to, had the case been handled right from the start. It is better to call the patient dead and to concentrate on his brothers and sisters. This is being done through the East Boston George White Health Unit and the schools. These youngsters report at regular intervals to the clinic, and a thorough check-up of the child by physical examination, roentgenogram and tuberculin test is obtained, along with a careful home and food history.

Let a doctor react in this way and at the same time be interested in individuals and one may be sure that he is doing his part in the fight against tuberculosis.

RHEUMATIC FEVER

On the seaboard, north of 40 degrees, as might be expected we are interested in the disease for which we can do the least: rheumatic fever, in its many manifestations and with its many tragic results. From our confused knowledge of rheumatic fever we grasp at the two straws that may possibly provide encouragement. The first of these is the conception that active rheumatic manifestations are responses on the part of the body to an engagement with the hemolytic streptococci. One has but to have this conception in mind to see it frequently exemplified in practice. For example, there is the notorious association of acute rheumatic fever with attacks of follicular tonsillitis, or the following situation, which was observed this year: A family of three children had all had scarlet fever and none of them had had serum treatment. Four weeks later one of them was suddenly stricken with fever and red, hot, tender, swollen joints. Was this a coincidence of rheumatic and scarlet fever, or could these have been two phases of the same episode? This question is asked rhetorically under these circumstances.

The other encouraging straw about rheumatic fever is the geographic variation in the incidence of rheumatic heart disease. A member of our department who went to medical school in Georgia likes to tell us of the discussion that centered about a case of heart disease in Atlanta—as to whether it was rheumatic or congenital heart disease. I believe the latter was decided on on the grounds of its greater prevalence!

This year we were fortunate in having Dr. Coburn accept an invitation to come from New York and give a lecture on the clinical and anatomic findings in fulminating rheumatism. We make no pretense of teaching the prevention of rheumatic fever, but we believe that an interest in the unsolved problems is quite as worth while as a recital of accomplished facts.

The more one explores it, the larger the field of clinical preventive medicine appears to be. I have touched on only the aspects of a few infectious diseases. There are many others. It would be fatuous to say that one can prevent the so-called degenerative diseases, and yet the treatment of some of them would seem to be the actual prevention of others. Thus, in middle age, obesity is the fibrinogen of diabetes and, to a lesser degree, of heart disease; once developed, diabetes is in turn precursory to arteriosclerosis and arteriolosclerosis, while in the background of all these are the various phases of the condition called hypertension. Here the therapeutic and preventive considerations merge together and make preventive medicine a mere point of view in the larger subject of clinical medicine.

SUMMARY

The fourth year teaching of preventive medicine at Tufts College Medical School is presented. Patients sick in their homes and cared for by the fourth year students, under supervision, are used as clinical material. The students have conferences with clinicians who are interested but not specifically trained in the science of public health. The opportunities for and the limitation of preventive measures are thus pointed out under the actual circumstances that confront the practicing physician. A few specific situations are discussed.

ABSTRACT OF DISCUSSION

DR. W. H. PERKINS, New Orleans: The use of the term "preventive medicine" has broadened in its general scope and has carried us back to the problem of the individual. Tremendous strides have taken place in prevention, but I believe that little further advance is possible in many of these efforts without the point of view which Dr. O'Hara has stressed. I am interested in the efforts that are being made in the different schools of this country to bring over Sir George Newman's dictum of "permeation of the entire curriculum with the preventive idea." Dr. O'Hara has shown us the light in one phase of this problem. It is excellent that the course which he has shown links up so closely with the medical department and uses much of its physical set-up. By taking the student into the domiciliary treatment and observation of his patients, a quicker revival of the family physician may be hoped for. Dr. O'Hara mentioned another thing. He is attempting to drive home to the students the necessity of seeking for more knowledge in order that the chain on many of these disease conditions which have a perfectly developing natural history may be cut. They have vulnerable points and any attack on those vulnerable points is really prevention. Those of us working in the broader aspect of public health welcome every possible effort to increase the student's conception of prevention. We hope that he may look on prevention with a broader vision than is shown in the textbooks. The other advantage of Dr. O'Hara's proposition is that the student gets into the home and thereby learns to send in good reports, which are the public health worker's medium of increasing his efforts. He is also looking in retrospect on the patient, wondering what could have been done to prevent the present condition, much as Dr. Leathers is doing at Vanderbilt. The effort of Dr. O'Hara and Dr. Pratt at Tufts is a step forward. Other solutions are certain to appear. I hope that papers on this aspect of prevention may continue to appear in the program.

Dr. J. E. Gordon, Detroit: The desirable correlation of clinical and preventive medicine is best developed in the education of the undergraduate medical student. Some stimulus must, however, be given the physician now actively in practice; otherwise the well instructed recent graduate may enter the larger professional group and there find his enthusiasm dulled by a general apathy toward preventive medicine. In the symposium of yesterday, in the joint meeting with the Section on Practice of Medicine, the observation was made that often the public is better instructed in recent developments of preventive medicine than the physician himself. In the attempt to interest actively practicing physicians in preventive medicine, the method too often is limited to dissemination of pamphlets, literature and lectures. I believe the graduate physician can obtain more benefit from actual demonstration of the related interests of clinical and preventive medicine, and of the possibilities of that correlation as it affects his individual private practice. In developing this idea, a series of clinical conferences was started in Detroit some years ago, to which all physicians were invited. The communicable diseases were selected as the subject best fitted for that demonstration. Twelve physicians attended the first meeting. In the course of three years that number has increased to as many as 382 physicians who attend these conferences at 10 o'clock each Wednesday morning. The clinics are a joint activity of the health department and the county medical society. Thus far communicable diseases, the venereal disease problem and tuberculosis have been discussed, apparently with a threefold result. The number of new cases of communicable disease has been limited by emphasis on preventive measures. Benefit has accrued to the patient ill with an infectious disease, through demonstration of present-day methods of diagnosis and treatment. Thus the effort toward lowered mortality has been directed not only to limitation of the number of cases, but to better care of patients already ill. Finally, a keener interest in public health problems has resulted from these conferences, as illustrated by the cooperative plans for diphtheria immunization and tuberculosis study presented in the scientific exhibit of this section. This has led to better case finding of communicable disease and I think better reporting of such conditions.

The Love of a Theory.—In rare instances the practicing physician becomes the creative scientist. His imagination conceives of an hypothesis, based on frequent, accurate, well controlled observation. This hypothesis is put repeatedly and rigidly to the test by carefully planned, albeit simple experiments on the human being. Many of the experiments of Harvey, the discovery of Jenner and the work of Laënnec were of this type. But science, for most men, does not progress much beyond the descriptive method, and knowledge is sought and obtained by accurate observations of natural phenomena, recorded with meticulous care, collected, compared, controlled by further observations, subjected to critical analysis, and finally brought to a conclusion uninfluenced by desire or theory. This method results in what is commonly known as experience, a word interpreted in the Middle ages as signifying experiment, and used today by the French to describe experiment. But at times, in experience and during experiments, desire warps judgment, and the love of a theory leads to disaster.—Longcope, W. T.: Methods and Medicine, *Bull. Johns Hopkins Hosp.* **50**:4 (Jan.) 1932.

RELATION OF PRIVATE MEDICAL PRACTICE TO PUBLIC HEALTH IN EUROPE

FRANK G. BOUDREAU, M.D.
GENEVA, SWITZERLAND

The relationship of the doctor to the public health is of the most vital concern at the present time; vital to society because national vitality is conserved and increased by adequate medical care; vital to the doctor because his professional welfare, his economic position and his personal well-being depend largely on the nature of that relationship. No one here would deny that the rights of society come first, the whole being greater than any of its parts. Nevertheless, society, in its own interest, owes to the doctor the right to practice his profession in conditions which provide for the best treatment for his patients and a position of dignity and of decent living for himself. That the relationship of the doctor to society is not in a satisfactory position must be apparent to the most casual observer. In America there has been set up a Committee on the Costs of Medical Care to inquire into this subject. The belief is general that certain classes of society, even in times of prosperity, are not fully provided with that degree of medical treatment, prophylactic and curative, which the advances of medical science have placed at the disposal of mankind. Large numbers of doctors, potentially capable of supplying such treatment, find themselves with idle hands and empty purses. Patients are unable to pay for adequate medical attention, while many doctors work desperately hard for a mere pittance. In America the cry is that the family doctor is passing away, while in Europe the doctor fears that the private practice of medicine is disappearing. It is obvious that the relationship of the doctor to the public health, to the state and to society is a subject of the greatest current importance and interest.

The increasing difficulty and complexity of that relationship are due, on final analysis, to the advances in medical science. Doctors and their colleagues in the allied sciences, in private practice, in salaried positions and in research laboratories have built up that body of knowledge which, with the growth of civilization, the state attempts to utilize for the public benefit. Advances in medical science have brought about an increasing specialism with its attendant problems. The need is felt for a recasting of the whole scheme of medical education, to endow the doctor with some part of the new body of knowledge and to fit him for proper performance of his public duty. The practice of medicine has long ceased to be a matter affecting only the doctor and his patient. It has become the concern of the state, which may adopt a policy of noninterference when all goes well, but which must take a hand when deficiencies of method or inequalities of application affect the public welfare.

POLICY OF EUROPEAN GOVERNMENTS REGARDING MEDICAL TREATMENT

Any student of public health and medical work in Europe must be struck with the importance which governments and the public attach to the liberal provision of medical treatment. The practice of medicine, or the adequate treatment of the sick, is considered to be the foundation on which rests the whole structure of public health work. Newman[1] spoke of the medical practitioner as our "first line of defense against disease." Such a potentially capable agent of society "cannot escape definite relationship with the existing system of public medical responsibility or fail to answer to the call of a wider sphere. For in whatever direction we look we find an ever-increasing burden of professional duty imposed upon him, with an ever increasing responsibility to his colleagues and to the state."

---

* Read before the Joint Meeting of the Section on Practice of Medicine and the Section on Preventive and Industrial Medicine and Public Health at the Eighty-Third Annual Session of the American Medical Association, New Orleans, May 12, 1932.

Believing that the primary public health problem is the early diagnosis and proper treatment of disease, European governments have adopted and enforced legislation for the public provision of medical treatment which has brought the doctor into a new and important relationship with the government. This tendency has its roots in the past. Beginning with the provision of casual medical relief for the destitute, it has developed and extended until a wide variety of medical treatment is offered freely to the public. The lesson that sickness is a disaster to the weaker classes of society, involving them in social and financial difficulties which the state ultimately will have to relieve, has been paid for dearly and is now fully appreciated.

PROVISION OF MEDICAL ASSISTANCE BY MEANS OF SICKNESS INSURANCE SCHEMES

If European governments concern themselves actively in the treatment of the sick, they do so indirectly so far as the largest groups of population are concerned, by means of sickness insurance. Social insurance is at present widely extended in Europe because of the public desire to protect the weaker classes—wage-earners, employees and their dependents—from sickness, invalidity and privation. It is a popular movement which has developed slowly throughout the years. With the growth of representative government and a developing humanitarianism, its pace has become much accelerated, and today sickness and invalidity insurance, its chief manifestations, are found in practically every European country, as well as in a number outside of Europe. Sometimes willingly, often protestingly, the medical practitioner has been drawn into the movement. No opposition offered by the medical profession has succeeded in halting its progress. Nevertheless, the medical provisions of sickness insurance have been modified and bettered at the suggestion of doctors organized into professional groups, and sickness insurance has succeeded best where it has had the loyal cooperation of a strong, highly trained medical profession.

I have stated that sickness insurance is a popular movement and that it is of ancient origin. Taking the Netherlands as an example, one finds that sickness clubs existed there as early as 1603 in connection with the guilds.[2] It had a similar origin in most of the countries in Europe. In its modern form sickness insurance dates back to 1883, when the first act legalizing it was passed in Germany. In the postwar period it took on new life, sweeping across Europe and extending overseas. There are two main forms of sickness insurance, the compulsory and the voluntary. In the compulsory form the law obliges persons following certain occupations or within certain income limits to join a sickness fund. This form is found in Germany, Austria, Hungary, Luxemburg, Norway, Yugoslavia, Great Britain, Russia, Czechoslovakia, Poland, Bulgaria, Portugal, Greece, France, the Netherlands, Chile and Japan.[3] However, the proportion of the population coming under the insurance scheme varies widely in these countries. In the voluntary form, no person is forced to join a sickness fund, but the state usually encourages the funds by various means, such as bonuses in respect of each member. This form is found in the Argentine, Belgium, Denmark, Finland, Spain, Sweden and Switzerland.[4] The tendency is for compulsory to follow voluntary sickness insurance. France is the latest convert to this system. Sickness insurance is only partial in Italy, where it is restricted to tuberculosis. It is but slightly developed in Spain. With these exceptions, it may be said that well developed schemes of sickness insurance are found in every important European country.

The object of sickness insurance is to spread the risk of illness among the socially weaker classes over a sufficiently large group, so that the cessation of earning power and the cost of treatment do not prove disastrous to an individual. The provision of medical treatment is its most important result. As the weaker classes of society are incomparably the most numerous, sickness insurance has inevitably made its influence felt in medical practice. More than three fifths of Germany's total population belong to sick funds or are entitled to medical treatment as the dependents of insured persons; 30,000 doctors, or 80 per cent of the whole number, work for the insurance funds, and for the great majority this work is the principal source of their income.[5] There are approximately 15,000,000 insured persons in Great Britain. Of the 7,600 doctors in Czechoslovakia, about 5,000 work for the sickness funds. Almost exactly half of the population is insured. In 1927, the medical profession received in fees from the sickness funds the sum of 238,000,000 crowns (over, $7,000,000).[6] In Denmark over 66 per cent of the entire population between the ages of 14 and 62 belong to sickness funds. Practically the entire wage-earning population of the Netherlands belongs to societies of medical help. About 50 per cent of the wage-earners in Belgium are insured. More than a fourth of the entire population of Hungary belongs to sickness funds; in Budapest the proportion is 80 per cent. As a rule, the insured proportion of the population declines in countries that are predominantly agricultural (Denmark is an exception), so that in Poland th[illegible] and in Yugoslavia only 3.5.[7]

[illegible] of sickness insurance is usually in the hands of sickness funds or societies made up of wage-earners and representatives of the employers. These are autonomous as a rule, state intervention being restricted to a varying degree of administrative and financial supervision. The resources of the funds are obtained by contributions from the members and employers with varying but usually limited financial participation of the state.

The benefits of sickness insurance vary not only from country to country, but also within a country. As a rule there are certain mandatory and a number of permissible benefits, the latter offered at the discretion of the individual funds. There is no legal obligation to give benefits to dependents of the insured, but on the continent the practice is general and is extending rapidly.

[6] Personal communication.

[7] These data are taken from Newsholme (footnote 2, vols. 1 and

Sickness insurance benefits are of two kinds: cash and medical, the latter word being used in its broadest sense. The cash benefit, usually amounting to one half of the basic wage, is paid for a varying period, in general about half a year if the illness lasts so long. In Great Britain medical benefit is limited to the treatment which a general medical pactitioner may reasonably be expected to give, but as a rule there is no such limitation on the continent.

Taking Germany as the classic example, the following is a list of the benefits which the insured may receive:[5]

Cash benefits.
Treatment by a general practitioner.
Treatment by specialists.
Hospital treatment.
Treatment in other institutions, such as convalescent homes, establishments for physical therapy and sanatoriums.
Use of such aids to diagnosis as the x-rays and laboratory examinations.
Dental treatment.
Supply of medicines, special drugs and diet, medical and surgical appliances.
Payment of allowance to the expectant mother and antenatal medical supervision.
Provision for attendance of midwife or doctor on confinement; care in maternity home if necessary.
Provision for after-care of mother and baby, including cash benefits; nursing benefit, to enable her to nurse her baby; proper food and, if necessary, treatment in a convalescent home.
Domestic help for mothers during confinement.

This is a summary list of the benefits accruing to the insured. It is not exhaustive. The dependents of insured persons receive most of these benefits, although benefits in cash are not paid to dependents. In 1925, more than 850,000 mothers in Germany received benefits on a more or less extensive scale from the various sickness funds, which contributed toward the expenses of nearly two thirds of the total births.

In providing the opportunity of complete medical treatment to such large groups, sickness insurance has become the main support of hospitals and other medical institutions, and has subsidized many forms of health work. In many European countries it determines the amount of the doctors' earnings and influences their distribution, so that an international conference on rural hygiene, convened last year by the League of Nations, decided that the best way to insure a sufficient supply of doctors in rural districts was to bring all agricultural workers within its scope.[8]

The contributions of sickness insurance are: social, preventing the disintegration of the family while the wage-earner is incapacitated; medical, providing the treatment necessary to restore health and working capacity, and prophylactic, which in addition to adequate medical treatment includes rest for the expectant mother before and after confinement, encouragement for her to nurse her baby and a variety of measures for infant and child welfare, tuberculosis and the venereal diseases. So strong are the sickness funds that of the three agencies concerned in certain branches of health work, the public authorities, private health agencies and the funds, the last often makes the greatest contribution.

RELATIONSHIP OF THE DOCTOR TO SICKNESS INSURANCE

The relation between sickness funds and doctors has not always been a happy one. There are, no doubt, many causes of friction which might be eliminated by judicious reforms. It would be unfair, however, to make a comparison between existing insurance medical practice and our conception of the ideal. Sir George Newman has said recently that contract practice was the forerunner of the English system of insurance, and when we consider the present insurance scheme we must compare it with the previous contract practice, the evils of which are well known to all of you.[1] In 1930, the British Medical Association went on record as favoring "The inclusion under the National Health Insurance service of the dependents of insured persons, provided that such an extended service include adequate safeguards respecting remuneration and conditions of service."[9] The adoption of this recommendation would bring at least 80 per cent of the total population of Great Britain within the insurance scheme.

While the doctors in some European countries frequently express dissatisfaction with the workings of sickness insurance, the belief is general that the conditions would be worse without it. In England the conditions of medical practice under insurance are determined by negotiation between the ministry of health and the medical profession. In many European countries the strong sickness funds negotiate directly with the doctors, who are in a relatively weaker strategic position. Moreover, this is apt to lead to great diversity of practice. In Germany, for example, doctors may be paid for each visit, they may receive a capitation fee per insured person, these capitation fees may be pooled and each doctor receive so much per visit, payment may be in respect of each case, fixed salaries may be paid or the doctors may be employed on a whole-time basis. In England, the doctor receives a capitation fee per insured person, and any licensed doctor may be inscribed on the panel. In Belgium, doctors may be paid for each consultation, or the insured may go to dispensaries set up by the funds. The dispensary system of treatment is highly developed in Poland, Czechoslovakia and Hungary, where the doctors are paid so much per hour.

The free choice of doctor has been a bone of contention between the doctors and the insurance funds. It is slowly gaining ground, and may be found in England and Switzerland and partially in Belgium, Denmark, Germany and Austria.

In Denmark, the doctors are apparently well satisfied with the insurance scheme. During a recent visit I talked with a number of them and their only complaint was that the less stable classes, who were often treated and left without payment, were not forced to come into the scheme. Danish doctors try to persuade their patients to join an insurance fund, while in the Netherlands many of the funds are organized by the doctors themselves. The medical provisions of the sickness insurance act in France were vigorously combated by the medical profession, with the result that important modifications were introduced. In its present form the law is not opposed by the organized medical profession, although a minority refuses to cooperate.

The limits of time and space do not permit me to discuss in detail the difficulties that have arisen between insurance funds and doctors, nor can I deal with the evils alleged to arise from the practice of sickness insurance. The whole subject has been discussed impartially and wisely by Sir Arthur Newsholme in his recent book "Medicine and the State." Those who wish for accurate information as well as shrewd analysis and constructive suggestion in regard to the practice of medicine, public health administration and sickness insurance will do well to consult this book as well as the three volumes of studies of European countries, which preceded it.[10] For complete information on sickness insurance I refer you to the publications of the International Labor Office, in which all the facts are recorded. But I cannot leave the subject without calling attention to certain medical advantages of sickness insurance not previously mentioned. It has mobilized large sums for the payment of medical fees from classes of the population not otherwise able to pay; it has limited its payments for medical treatment to qualified practitioners, thus discouraging quackery. It has stabilized the income of physicians. In times of depression it has provided fees for doctors which otherwise they would have been unable to obtain, and the major part of its resources is devoted to payment for medical treatment.

---

[8] Report of the European Conference of Rural Hygiene, Health Organization, League of Nations, vol. 1, 1931, p. 21.

[9] Newsholme, Arthur: Medicine and the State, Baltimore, Williams & Wilkins Company, 1932, p. 132.

Since it is agreed by most authorities that large groups of the population cannot afford the immediate cost of that complete medical treatment which the advances of medical science have placed at our disposal and that some of its cost must come from the proceeds of taxes, the value of a contributory scheme seems to be beyond question.

No matter what our individual views may be, it cannot be denied that sickness insurance is spreading rapidly. Its development in any given state may be summed up in a few words; growth of friendly societies, legislative recognition of their value and importance, attainment of full-fledged voluntary insurance with government encouragement and supervision, realization that those who need it most do not join the sickness clubs and the adoption of the principle of compulsion. In view of the fact that doctors often favor sickness insurance but object to medical benefit, it may be of interest to note that in the Irish Free State the highly developed system of public medical assistance provides home and institutional treatment for almost half the population in some districts. It is, in the main, a dispensary system supported by public funds, and medical treatment of the insured does not come within the scope of the insurance scheme in Ireland.[11]

THE MATERNITY SERVICE

Another indication of the fact that European governments consider medical treatment of fundamental importance in public health promotion is the large public provision they have made for maternity. The general practice is the provision of midwife service and, if necessary, of the services of a doctor for all pregnancies. I do not mean to imply that all such service is free. As a rule, payment is exacted from those able to pay. But the governments provide for the appointment of a sufficient number of salaried and official midwives to insure that their services may be everywhere available. Institutional treatment for maternity, much of it at the public expense, is becoming a common practice.

The virtual monopoly of normal obstetrics in Europe by the midwife is striking. In Great Britain over 60 per cent of births are attended by midwives. The proportion is about the same in the Netherlands, which has a well organized midwife service. Candidates for the service are carefully selected and trained; the government pays for their education and maintains them during their training; it also restricts their number.[12]

In Denmark,[12] district midwives are appointed, and the government requires their services to be everywhere available. They attend nearly all normal deliveries even in the upper classes. In Sweden [12] there are apparently more midwives than doctors; half of them are salaried officials, and they attend a large majority of all births. The system is about the same in Norway, where in 1927 midwives attended more than 90 per cent of the total of more than 50,000 births. The puerperal death rates in the Scandinavian counties and Holland are remarkably low, not usually exceeding 3 deaths from all causes per thousand live births. As a rule, midwives are not permitted to use forceps. Moreover, a doctor is almost always at their call. In Norway, the midwife works under the district medical officer. In Prussia, nearly 90 per cent of births are attended by midwives.

The practice of medicine in Europe must be profoundly affected by the presence of such large numbers of well trained midwives, by their appointment as salaried officials and by the custom of calling midwives for nearly all confinements. The result is that the ordinary practice of medicine does not include normal obstetrics. The low rates of puerperal mortality in countries with a well organized system of midwives does not necessarily reflect any discredit on the doctor as an obstetrician. My view is that it demonstrates the value of making available skilled obstetric service throughout the country and to all classes without regard to their financial resources. Sir Arthur Newsholme's views are summed up in the following statement:

"There is exceptional safety in childbirth the care of which is undertaken by trained midwives, who have skilled medical help available when complications render this necessary." He also stated: "Thus the international practice in virtue of which midwives care for the vast majority of normal confinements in Europe is associated with an exceptionally favorable maternal experience." [13]

THE NOTIFICATION OF TUBERCULOSIS

Two important public health problems of great interest to the medical practitioner are tuberculosis and the venereal diseases. The practicing physician is usually concerned with the campaign against tuberculosis in two of its aspects: the notification of the disease and its treatment by the public authorities. It is notifiable in Great Britain, where specialists, often whole time, are employed by the local authorities as tuberculosis officers. In France its notification is facultative; the Academy of Medicine favors obligatory notification, but the ranks of the medical profession resist. This is bound up in France with professional secrecy or the "medical secret," which the profession considers should bind its members. The doctors even object in principle on this ground to the certification of causes of death, and in consequence vital statistics in France are incomplete. This difficulty has been gotten over in some French departments by the adoption of the Swiss system, in which certification of the cause of death is absolutely confidential and separate from the certificate attesting to the fact of death. In Switzerland, the doctor is required to notify cases of tuberculosis which are a public danger. There is compulsory notification of tuberculosis in some German states. It is not notifiable in the Netherlands. In Denmark, respiratory tuberculosis is a notifiable disease.

[10] Newsholme (footnote 2), based on studies carried out on behalf of the Milbank Memorial Fund.

[11] Newsholme (footnote 9, p. 141).

[12] Most of these data are taken from Newsholme (footnote 2).

[13] Newsholme (footnote 9, pp. 170 and 171).

The notification of disease in the Scandinavian countries is worthy of special attention. There is immediate notification of certain diseases, while weekly or monthly notification of all new cases seen by the doctor is required. No names or addresses are given except for patients with infectious diseases. The doctor receives no payment for these returns; indeed, compensation for notification of disease appears to be restricted to England and one French department.

The system of vital statistics in Scandinavia is altogether admirable. Any one who wishes to study the movement of disease over long periods of time must turn to these countries, where he will find by far the oldest and most complete records. The success of the system is largely due to the loyal and unselfish cooperation of the medical profession.

THE TREATMENT OF TUBERCULOSIS

Antituberculosis dispensaries are multiplying rapidly in European countries. Some figures for 1928 will give an idea of their number.[14] In that year there were 655 in England and Wales, 202 in Poland, 242 in Italy, 2,089 (1926) in Germany, 640 in France and 70 in Austria. As a rule, no treatment is given by these dispensaries, which are intended mainly f [illegible] preventive social work. In Belgium, [illegible] saries are in the hands of a private health agency, treatment is given, but there has been no friction with the doctors. In Italy there is compulsory sickness insurance against tuberculosis. All those who are insured against invalidity and old age must join, and the scheme also includes the family of the insured. In Hungary and Poland persons with tuberculosis are treated at sickness insurance dispensaries and university clinics. In the cities of Europe, antituberculosis dispensaries are in charge of specialists, and this is true also in rural districts to an increasing extent.

The first establishment of such dispensaries was opposed by the medical profession in many countries, and this was true also of the gradual displacement in their management of general practitioners by specialists. This opposition has died down, and private practitioners now utilize such dispensaries to an increasing extent. Such is the case in France, where the present dispensary system of dealing with tuberculosis was originated by Calmette at Lille in 1905. The development and extension of the system aroused much controversy, the medical syndicates desiring to have the dispensaries controlled by local general practitioners, who would take turns in attending them. This position was untenable, and specialists now direct the dispensaries.

At this point I must refer to the decision of an international conference on rural hygiene which met last year at Geneva. There were official delegations, most of them including doctors, from twenty-three European states. The conference adopted the following resolution, which had been prepared by a committee consisting of three representatives of medical associations from France, Germany and Spain and six other members.

> The rural population and rural doctors should be in a position to utilize the services of centers of diagnosis and if necessary of specialized treatment (for tuberculosis and venereal diseases); such centers should be suitably equipped and provided with a qualified staff.
>
> These services should maintain liaison with the patient's physician, who should be informed of the results of the examinations, or, if necessary, kept in touch with the treatment and its results.

This resolution may be regarded as the official doctrine in Europe.

I wish to make one further comment in closing the section on tuberculosis. When, under the sickness insurance system, the doctor is paid a capitation fee per insured member he loses nothing when he refers his tuberculous patients to the dispensary, hospital or sanatorium.

THE VENEREAL DISEASES

The notification of venereal diseases is not general in Europe, but it is a fairly common practice to require the doctor to notify patients who discontinue treatment before its completion. Sweden, Hungary and Norway, where notification is compulsory, are exceptions. On the other hand, free treatment of venereal diseases is fairly common and is rapidly gaining ground. Denmark is the classic example, for here it began in 1790 and has continued and extended ever since. Every one in Denmark, regardless of class or resources, has the right to free treatment. Such treatment is part of the official duty of salaried district medical officers, of whom there are 70. There is, however, still some treatment of patients by private practitioners. Sweden has followed the example of Denmark. There are polyclinics with specialists attached in all towns with populations in excess of 20,000. In the rural districts treatment is given by the district medical officers. In both Denmark and Sweden the right to free treatment is accompanied by the obligation to pursue treatment, and penalties for discontinuing treatment are enforced. The compulsory notification is followed up by attempts to locate the source of the disease. These were successful in 60 per cent of a large series of cases. Private practitioners do not object to the polyclinics, as the publicity attached to them is said to stimulate a large amount of remunerative private practice. The prevention of venereal diseases in Belgium is based largely on the cooperation of the medical profession, 27 per cent of whom are entitled to receive supplies of arsenicals without cost. Doctors who treat such patients gratuitously are expected to report them and to accept possible supervision by a government medical inspector. Private exceeds public treatment of patients with venereal diseases, and no friction has been created. There has been no general adoption of gratuitous treatment by the German states, as 80 per cent of the cases come under the insurance scheme. The multiplication of centers for treatment in Berlin aroused the opposition of the medical profession.

Newsholme stated that the medical profession in England "has cordially accepted the principle of the gratuitous treatment, at clinics supported from public funds, of all applicants who have a venereal disease."[15]

In Italy the law requires the chief town of each province and all towns over 30,000 to be provided with antivenereal dispensaries. Hospitals are required to treat patients with the disease in the infectious stage, and the state pays the cost of such treatment.

In France the state has provided large sums for antivenereal work, and dispensaries have been established all over the country. There is much free treatment, but patients able to pay are expected to do so. Private practitioners may treat such patients at the public expense under regulation.

This brief summary shows that the public authorities in Europe are rapidly becoming convinced of their responsibility to insure effective treatment for persons with venereal diseases. Such treatment is regarded as the best means of prevention, and free treatment, as a means to this end, is rapidly becoming more common.

---

[14] These data are taken from the International Health Year Book, Health Organization, League of Nations, 1928

[15] Newsholme (footnote 2, p. 214).

INFANT WELFARE WORK

Maternal and infant welfare dispensaries or consultations are found in most European countries. They are organized by the public authorities, sickness insurance funds and private health agencies. The following figures give some idea of their numbers.[14] In 1928, there were 4,050 in France, 2,769 in England and Wales, 450 in Belgium, 446 in Germany, 218 in Poland, 177 in Hungary and 110 in the Netherlands. In cities these consultations are usually in charge of specialists, but in rural districts the majority are under the direction of private practitioners. As a rule, no treatment is given, patients being referred to their family doctors, so there has been little friction with the medical profession. There is one notable exception to the rule that no treatment is given by such centers: in France and a number of other countries B C G is administered.

The centers I have been discussing are really well-baby centers. It is unlikely that much of this work would find its way into the hands of general practitioners in any case. It is physiologic rather than pathologic and preventive rather than curative. The same holds true of the treatment of defects found as a result of school medical inspection, which is the concern of specialists rather than of general practitioners.

MEDICAL INSPECTION OF SCHOOL CHILDREN

Medical inspection in the schools is fairly well established in the larger European cities, but is much less developed in the rural districts. In England and certain parts of Germany it is highly developed. As a rule, the inspections are carried out by private practitioners who are paid for part-time work. There is a tendency in some countries to replace the part-time practitioner with the official whole-time school medical inspector. This has led to some friction with the medical profession, notably in Belgium and Germany. The educational authorities in England provide treatment for which a small charge is made, but on the continent the children requiring treatment are referred to private doctors, hospital dispensaries or insurance fund polyclinics. It may be of interest to point out here that in three Swiss cantons sickness insurance for primary school children is compulsory. There is limited free choice of physician, and the children go to the doctor's office or are visited in their homes. Disputes over the scale of fees have occurred between the doctors and the funds, but this is now adjusted. A similar law is proposed in Yugoslavia. The combination of such a scheme with an efficient system of school medical inspection would go far to solve the problem of school hygiene. There is one exception to the statement that in Europe no treatment is given by school medical inspection systems; school dental clinics are common and do much work, but have aroused little opposition.

IS THE DOCTOR EQUAL TO THE TASK ENTRUSTED TO HIM BY SOCIETY?

It has been shown that a heavy responsibility is placed on the doctor by the public authorities in the majority of European countries. The work of the doctor is the key to the success or failure of sickness insurance funds, which he can seriously damage by overcertification of illness and perfunctory treatment or foster by a steady adherence to his difficult duty. His is not the only responsibility; it is shared by the insured, who must understand the aim of group insurance if it is to be successful. I believe that a large majority of the medical profession fully lives up to all that is expected of it within the limits of its own possibilities. It is only a small minority which is responsible for abuses.

Does the doctor in his daily practice apply the most modern principles of treatment and prevention? This, of course, is a counsel of perfection; nothing so ideal can be expected of human beings. It is said that the preventive results of sickness insurance which were confidently expected in England and other countries have not been fully realized. If this be true it is not altogether the fault of the doctor, to whom society owes certain facilities for medical practice, suitable material conditions, proper equipment and adequate public provision for relief and institutional care. Moreover, the doctor's training may not fit him for the important part he is to play in the complicated organization of modern society.

As a result of a number of requests, the League's Health Organization has set up a committee on medical education, and as a first step has obtained from a few medical leaders in Europe reports on the training of doctors in the several countries. Dr. G. Roussy, dean of the Faculty of Medicine in Paris, wrote:[16] "Nothing, in practice, is done to prepare the doctor for his social duties. The reform of medical education is the order of the day in all countries. It is imperative for the following reasons:

"(1) The evolution and constant progress of medical science;

"(2) The new trend of modern medicine which has hitherto been essentially curative, but which is becoming to an ever increasing extent, preventive and social."

According to Prof. J. Tandler of Vienna,[17] "Complaints regarding the inadequacy of medical training and the consequent proposals for reform in this field were already heard before the war and have since become clamant." After discussing these proposals, he said: "All the reforms suggested up to the present will, however, prove inadequate, unless the need is realized of familiarizing a doctor with the social structure of the society in which he lives." Dr. Carl Prausnitz,[18] director of the Social Hygiene Academy at Breslau, noted that "a revision, and extension of (medical) training is long overdue." Sir George Newman,[2] chief medical officer of the ministry of health and board of education in England, pointed out that in medical education, "The preventive aspects of medicine are sometimes neglected. It is assumed that prevention and prophylaxis is the function of the public medical officer and is necessary only for a diploma in the public health field. There never was a greater misapprehension."

These quotations give a partial answer to my question; there is evidently a somewhat general feeling that the present methods of medical education do not adequately prepare the doctor for his heavy social responsibilities.

The League's Health Organization has also convened conferences of directors of schools of hygiene from time to time. These, while concerned primarily with the training of medical officers of health, have adopted recommendations on the public health instruction of

medical students, for, in the words of the directors:[19] "It is to the main body of general practitioners that the public must look for personal guidance in the prevention and detection of disease." The recommendations, too detailed to reproduce here, insist that every professor in medical schools should "constantly emphasize the preventive aspects of his particular subject; this aspect should, in fact, pervade the entire medical training." Practical experience for the student in the various branches of dispensary and social work is also recommended. Refresher courses in preventive medicine are advised for the general practitioner as well as for the part-time medical officer of health.

I have made no reference to conditions in Soviet Russia, because I have never visited that country. I am told that it is the intention of the government to wipe out private medical practice and to replace it by salaried state doctors. Even now private practice has almost completely disappeared. The complete reform of medical education is of some interest. The old type of medical school no longer exists. It has been replaced by the following three faculties:

1. Therapeutics and prevention.
2. Hygiene and sanitary technic.[19]
3. Maternal and infant welfare.[20]

It is the hope of the Soviet government that these new faculties will turn out doctors suited to the work they will be required to do. I offer this information without comment.

In presenting these facts about the doctor and his relation to the public in Europe today, I have tried to be as objective as possible. I have omitted many facts and may have overemphasized certain others; I do not claim to have given a complete picture. It would be dangerous to attempt to draw any general conclusions, and I propose to restrict my concluding comments to a few brief statements.

In the principal European countries today, society is recognizing to an ever increasing degree its public responsibility for the health of all classes.

The public authorities are laying increasing emphasis on the adequate provision of medical treatment as the basis of the public health.

The private practitioner is being drawn yearly into a closer relation with the government and its public representative authorities.

No difference of opinion can be held as to these facts.

This change in the relationship between society and the doctor has from time to time created friction and dissatisfaction, usually most intense at the beginning of any social or medical reform. This dissatisfaction has died down, as a general rule, with the passage of time and the introduction of modifications suggested by practical experience.

The least dissatisfaction is found where the medical profession is conversant with public social and medical problems and is united into strong but not narrow professional groups, and where the public authorities keep the doctors in touch with the purposes of their proposals.

In the countries where society has made the greatest demands on the doctor, where the old forms of private practice have most diminished and, if you will, where the socialization of medicine has made the greatest progress, the moral and material position of the doctor has not visibly suffered. On the contrary, he is often more highly regarded and his reward is relatively greater in proportion to the heavier but more honorable social responsibilities which he has been called on to assume. "For it is true today as it has never been true before that one can serve himself only by serving the community. The social outlook and socialized behavior are demanded of contemporary man not merely, nor even primarily, on grounds of justice and mercy, but of the most self-centered and materialistic wisdom."[21]

EFFECT OF KNEE-CHEST POSITION AND POSTURAL EXERCISES ON POSTPARTUM RETROVERSION

GOODRICH C. SCHAUFFLER, M.D.
PORTLAND, ORE.

Clinical observation of the results of measures empirically prescribed to curb postpartum retroversion suggested that this empiricism might be without basis in fact. Therefore controlled observations were started.

Certain factors appear to favor the production of postpartum retroversion. The tendency toward descensus inherent in the mechanism of labor weakens the supports of the uterus and draws it down, swinging the corpus into a type of retroversion that is identical with early prolapse.

Following delivery, the uterus is normally in a position approximating first degree retroversion. Theoretically, this tendency is increased through the dorsal posture of the patient in bed, which is more or less routine. The natural tendency of the heavy corpus to drop back against the sacral promontory is thus accentuated.

Subinvolution increases this tendency. The size and weight of the congested uterus (with the patient on her back) work against the normal tendency toward anteversion exerted by shortening of the anterior uterine wall and contraction of the round ligaments.
These two factors are a part [illegible] nal involution.
The persistence of subthreshold [illegible], injury to the

suggested on the ground that the reported observations are the result of a single examination. However, it was found inadvisable to use statistics from subsequent examinations for purposes of this study, since more effective measures were immediately instituted to control retroversion. I refer to replacement, the use of pessaries and decongestive measures, all tending to obscure later observations. Doubtless, in some instances, spontaneous corrections would have been noted later. It is generally conceded that, barring abnormal factors, involution and return to the normal anterior position should have occurred by the sixth week. Therefore, our report is based on examinations made at this time.

NUMBER OF CASES

I wish to emphasize, first, that 169 cases comprise a small group on which to base conclusions. It is, however, a sufficient number to warrant comment and should successfully upset dogmatic teaching based apparently on speculation and argument from analogy. Certainly there is little in the nature of controlled experiment to support current teachings.

TYPE OF CASE

The cases that constitute the basis of this study were taken from consecutive deliveries at the Salvation Army White Shield Home. The patients were nearly all vigorous young women (about 90 per cent primiparous) and presented a group practically free from complicating factors such as retroversion from previous pregnancy, prolapse, and the like. The only considerable complicating factor consists in possible congenital or traumatic retroversion. The incidence of such conditions should be equal in our test and control groups and therefore is negligible in this study.

SELECTION OF CASES AND TYPE OF EXERCISES

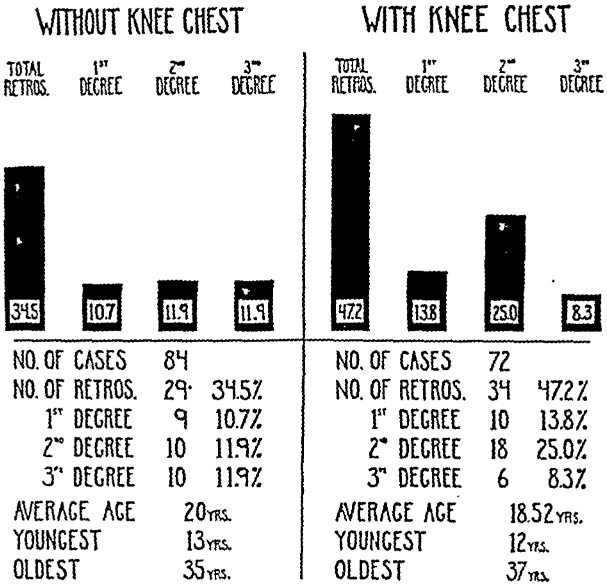
Patients were numbered in the order of their delivery. Alternate patients (odd numbers) were put on a special regimen consisting of the ventral posture in bed, and the knee-chest position beginning on the eighth day post partum and increasing to twenty minutes twice a day. On the eighteenth day they were started on the camel walk, and instructed to rest as nearly as possible entirely on the abdomen while in the prone position. Conservative abdominal exercises in the upright posture were also prescribed. As far as possible, these procedures were supervised. Naturally, some patients were less faithful than others, but on the whole it would be difficult to obtain a better regulated and supervised group.

The even number patients were given no exercises whatever, and no instructions in regard to prone posture, and were directed not to undertake any such measures on their own initiative.

EFFECT OF KNEE-CHEST POSITION

The accompanying chart shows that the incidence of retroversion following the use of the knee-chest position has been 47.2 per cent as opposed to 34.5 per cent in the cases in which the knee-chest position was not used. There is room for a certain variation due to chance in as small a group of cases as this. However, there can be no question that the value of such exercises as described has been in the past vastly overestimated. Perhaps it is unfair to conclude from this series that the use of the knee-chest position actually increases the incidence of postpartum retroversion. On the other hand, the confidence that has always been placed in it as a therapeutic measure is no longer justified. It seems fair to conclude also that, since in this type of case postural exercises should be the most effective mechanically, owing to the heaviness and size of the corpus, the use of the knee-chest position in other types of retroversion would be even more futile.

If one chooses to put implicit confidence in these figures, then one must search for factors in the use of such exercises that might actually retard involution and favor retroversion. It is conceivable that the trauma due to early movement and disturbance of the pelvic structures with possible retardation of circulatory rehabilitation might act in such a way. It is quite possible that the natural forces of reconstruction may work better with the uterus in the vertical position, splinted by the sacral promontory, than under circumstances in which it is frequently teetered forward into an anterior position (perhaps unphysiologic at this time). As an analogy may be cited the potential harm in too early attempts to obtain complete flexion in an injured joint. These are merely speculations, but they may have some bearing on our rather surprising results.



WITHOUT KNEE CHEST			WITH KNEE CHEST

Effect of knee-chest position on postpartum retroversion.

We feel added confidence in the result of these studies from the fact that check figures during the eighteen months taken for the experiment showed a constantly higher number of retroversions following the use of the knee-chest position. This should eliminate the possibility of a temporary variation due to chance.

The percentages that I have mentioned have been for the entire group of retroversions. It is of interest to note that the majority of retroversions have been second and third degree. This definitely establishes the fact that our observations are not influenced by a large group of borderline cases. If a large majority of these cases had been first degree retroversions there would be considerably more doubt as to the significance of our results. It will be noted in the chart that there is an incidence of 25 per cent of second degree retroversions following the use of the knee-chest position as opposed to 11.9 per cent in cases in which the knee-chest position has not been used. This discrepancy is even more marked than that in the total group. Since the second degree retroversion may be considered the average or the mean of the entire group, these comparative per-medical students, for, in the words of the directors [19] "It is to the main body of general practitioners that the public must look for personal guidance in the prevention and detection of disease" The recommendations, too detailed to reproduce here, insist that every professor in medical schools should "constantly emphasize the preventive aspects, of his particular subject, this aspect should, in fact, pervade the entire medical training" *Practical experience for the student in the various* branches of dispensary and social work is also recommended Refresher courses in preventive medicine are advised for the general practitioner as well as for the part-time medical officer of health

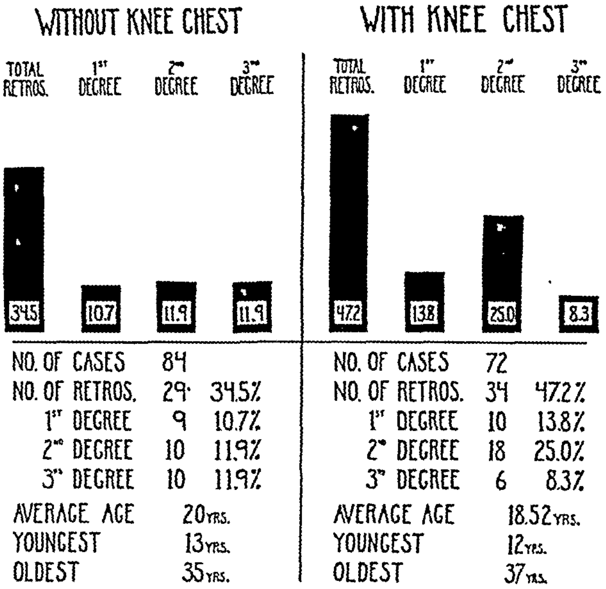
As an analogy may be cited the potential harm in too early attempts to obtain complete flexion in an injured joint. These are merely speculations, but they may have some bearing on our rather surprising results.



Effect of knee-chest position on postpartum retroversion.

We feel added confidence in the result of these studies from the fact that check figures during the eighteen months taken for the experiment showed a constantly higher number of retroversions following the use of the knee-chest position. This should eliminate the possibility of a temporary variation due to chance.

The percentages that I have mentioned have been for the entire group of retroversions. It is of interest to note that the majority of retroversions have been second and third degree. This definitely establishes the fact that our observations are not influenced by a large group of borderline cases. If a large majority of these cases had been first degree retroversions there would be considerably more doubt as to the significance of our results. It will be noted in the chart that there is an incidence of 25 per cent of second degree retroversions following the use of the knee-chest position as opposed to 11.9 per cent in cases in which the knee-chest position has not been used. This discrepancy is even more marked than that in the total group. Since the second degree retroversion may be considered the average or the mean of the entire group, these comparative percentages lend some strength to the hypothesis that there may be factors in the use of the knee-chest position actually antagonistic to normal involution and anteversion.

The percentage of retroversion in this entire group, including tests and controls, is in general accord with other figures for similar groups. I have not, however, found any other critical studies covering this particular field and therefore think these observations worthy of note. Further study in the same field is indicated.

SUMMARY AND CONCLUSIONS

1. Alternate patients (odd numbers) in a group of 169 deliveries were put on knee-chest position and postural exercises, whereas alternate patients (even numbers) were not given such measures.
2. Examination after six weeks revealed a substantially higher incidence of postpartum retroversions in the group subjected to the so-called corrective measures.
3. It is fair at least to conclude that the use of such exercises does not justify the confidence which has formerly been placed in them.
4. It seems wise even to seek for factors in the use of such exercises that may actually retard the tendency toward involution and return to the normal anterior position.

Clinical Notes, Suggestions and New Instruments

CIRRHOSIS OF THE LIVER CAUSED BY CARBON TETRACHLORIDE

Winfield L. Butsch, M.D., New Haven, Conn.

Carbon tetrachloride has a widespread use with apparently little attention accorded to its danger as a toxic agent. Out of this neglect has appeared a case of cirrhosis of the liver similar to the experimental cirrhosis produced in dogs by the same substance. Although there are numerous records of acute yellow atrophy caused by carbon tetrachloride, no instance of liver cirrhosis has been reported in the literature.

The poison was assimilated by the patient through inhalation while at work. Lamson[1] has produced a similar effect by immersing dogs in a concentrated vapor of carbon tetrachloride repeatedly over a period of one month. Autopsy of the animals showed the liver lesion to be one of healing central necrosis with stellate areas of collapsed framework about the hepatic veins. The adjacent liver cells in a wide band contained fat droplets.

Bollman and Mann[2] in their work on experimentally produced lesions of the liver demonstrated that, with repeated sublethal doses of carbon tetrachloride, increasing injury to the livers of dogs resulted in the production of most of the symptoms characteristic of portal cirrhosis. Gastro-intestinal upsets, diarrhea and intestinal hemorrhages were the first symptoms observed. The excretory function of the injured livers was marked by a definite retention of dye.

REPORT OF CASE

An American laborer, aged 54, entered the hospital with complaints of a large abdomen, morning nausea and weakness. Six months previously he had been transferred to a position requiring the cleaning of old telephones with a solution containing 60 per cent carbon tetrachloride and 40 per cent gasoline. This was done in a poorly ventilated room, where the fumes arising from the cleaning solution were unmistakable. He found himself frequently giddy with an aching head toward the close of the day, and often nauseated when he returned home for the evening meal. After he had been at this work for two months, a period of intractable diarrhea which lasted three weeks occurred and his abdomen began to increase in size. Five weeks before admission he developed morning nausea and weakness, accompanied by loss of sexual libido. A dry irritative cough appeared with small amounts of stringy, whitish sputum. All the other men engaged at this work developed symptoms of nausea, dizziness and lack of appetite, and asked to be transferred from time to time. The patient remained on duty.

The patient was large, well developed and well nourished. His complexion was pale. He did not show prostration. The positive observations were limited to the abdomen, which was enlarged and globular with dilated veins coursing over its upper half. Shifting dulness was noted in the flanks, accompanied by a fluid wave. The liver and spleen were not palpable at the time.

The positive laboratory observations of especial reference to this case were as follows:

Van den Bergh test: direct, negative; indirect, 1.1 mg. per hundred cubic centimeters.

Bromsulphalein function test: 50 per cent retention at end of five minutes; no retention at end of thirty minutes.

Blood fat: admission, 1,245 mg. per hundred cubic centimeters estimated as tripalmitin; three weeks later, 765 mg.

Serum cholesterol: admission, 856 mg. per hundred cubic centimeters; three weeks later, 563 mg.

Again the work of Mann on dogs proved to be of great value in suggesting the treatment of the case. In dogs in which ascites developed after experimentally produced cirrhosis, Mann was able to induce the absorption of the ascites with restriction of meat and the feeding of large amounts of carbohydrates. He then could almost at will cause alternately the formation and removal of ascitic fluid by alternating these two foods in the diet.

Accordingly, the patient was placed on a high carbohydrate diet with restriction of all meats. Urea produced a moderate diuresis. At the time of discharge, one month later, he had regained his libido and felt stronger. His abdomen had decreased in girth from 42 to 40 inches. At no time did the patient have a febrile temperature or evidences of clinical jaundice.

He returned for observation at monthly intervals.

One month later he was back at work with his strength returning very slowly. No shifting dulness was noted. The liver and spleen were not palpable. His appetite was poor. Dilated veins were still prominent.

Two months later he felt somewhat stronger though the cough persisted. The liver was palpable 4 cm. below the costal margin in the midclavicular line. He was allowed meat twice a week. The blood fat was 702 mg. per hundred cubic centimeters.

Three months later he felt much stronger and his appetite had improved. The abdominal veins were much less prominent. The liver was palpable 2 cm. below the costal margin. The spleen was not palpable. The abdominal girth was 39 inches. He was allowed meat every other day.

Four months later he was feeling strong enough to work in the garden in his spare time. His appetite was good. The liver was palpable at the costal margin. His abdominal girth was 38½ inches. Since discharge, his weight had remained stationary at 180 pounds (81.6 Kg.). The blood fat was 497 mg. per hundred cubic centimeters.

COMMENT

Although there was no conclusive evidence in this case of a cirrhotic liver, it seems reasonable to presume the diagnosis to be correct in view of the characteristic symptoms and the signs of portal obstruction following close on the exposure to carbon tetrachloride.

In connection with the lipemia, it is interesting to note the observations in a case reported by MacMahon and Weiss,[3] in which an autopsy was performed in a case of acute yellow atrophy in which the patient died five days after the accidental

[3] MacMahon, H. E., and Weiss, Soma: Am. J. Path. **5**: 623 (Nov.) 1929.

ingestion of carbona. It was found that 64 per cent of the blood in the pulmonary artery and 25 per cent of the blood in the inferior vena cava was fat. Rosenthal and Lillie[4] noted that out of seven dogs given carbon tetrachloride orally one developed a spontaneous lipemia (estimated by the appearance of the blood only).

In view of the frequent use of carbon tetrachloride as a solvent in the dry cleaning and rubber industries and as a general cleaning solution, it is noteworthy that chronic liver injury may occur under conditions in which large amounts are inhaled.

METHOD FOR DIAGNOSIS OF AMEBIASIS

Alfred C. Reed, M.D., and Herbert G. Johnstone, A.B., M.S.
San Francisco

The diagnosis of amebiasis rests solely on the microscopic identification of the pathogenic ameba Endamoeba histolytica. This identification requires special technical skill and experience. An unqualifield technician is entirely unreliable and may be dangerous. Few laboratories and fewer physicians have available a properly qualified and reliable technician. Unless diagnosis can be made properly it is much safer not to attempt it at all.

Furthermore, ordinary stool specimens must be examined for amebic cysts within forty-eight hours as the chromatoidal bodies disappear and the cysts break up, so that positive observations become less as time progresses. A large percentage of patients with amebiasis, even in the absence of diarrhea, show motile amebas, together with cysts or alone. Motile amebas die quickly and only immediate examination of the fresh stool specimen will demonstrate them. It is always desirable to examine a series of specimens, at least covering six consecutive days. If the first tests are negative, the patient should receive epsom salt in small amount with examination of the fresh soft stools. When amebiasis is suspected, sigmoidoscopic examination should be made and swabs taken from ulcers. If no ulcers are seen, mucus or fecal material from the sigmoid wall should be examined directly for amebiasis.

Finally, certain identification of the ameba is best done with the use of the iron hematoxylin stain, which should be a routine procedure in stool examination for protozoa. This staining method is long and complicated and requires special technical skill.

We have found in practice that it is possible to follow a routine method for diagnosis of amebiasis which will obviate all the difficulties enumerated and meet all the requirements for accurate diagnosis. This method depends on the preparation of smears by the attending physician directly from the patient, in such form that motile amebas are preserved as well as cysts, and swab specimens from the sigmoid can be utilized as well as ordinary fecal specimens. These wet smears are sent to a central reliable laboratory for staining and study.

This method has been described by William M. James[1] and was developed on the basis of previous reports and recommendations of Dr. C. A. Kofoid. It is easy for the physician to prepare and keep on hand the few solutions necessary and a supply of proper containers. The method can be summarized as follows:

A small amount of the fresh stool specimen is spread on a clean flamed slide with a paste brush. The strokes should be made parallel to the longer edges of the slide to facilitate microscopic examination. The pressure should be so regulated that the material shall be spread thinly, eliminating all lumpy particles. Approximately 1½ inches of the surface length of the slide should be covered. Before the slide is allowed to dry, it is immersed immediately in Schaudinn's fixing fluid.[2] The slide can either remain for ten minutes in the fixing fluid heated to 60 C. or be kept over night in the fluid without heating. The slide is then placed for ten minutes in 70 per cent alcohol tinged to a wine color with compound solution of iodine. Following this, the slides are placed in 70 per cent alcohol for five minutes and then put in bottles containing 70 per cent alcohol, for mailing. A rubber band should be placed round each end of the slide to prevent breakage. In addition, a piece of absorbent cotton should be packed on the top of the slides to eliminate as much movement as possible. Each slide should be properly marked with a diamond pencil. Pure ethyl alcohol must be used, and at no time should the smears be allowed to dry. The bottle containing the slides is put in a screw top cardboard mailing container and sent to the laboratory to be stained (iron-hematoxylin) and examined.

350 Post Street.

Committee on Foods

The following products have been accepted by the Committee on Foods of the American Medical Association following any necessary corrections of the labels and advertising to conform to the Rules and Regulations. These products are approved for advertising in the publications of the American Medical Association, and for general promulgation to the public. They will be included in the Book of Accepted Foods to be published by the American Medical Association.

Raymond Hertwig, Secretary.

SQUIBB DEXTRO-VITAVOSE

(Dextrose and Malted Wheat Germ Extract)

Manufacturer.—E. R. Squibb and Sons, New Brunswick, N. J.

Description.—A powdered mixture of dextrose and extract of malted wheat germ and U. S. P. malt; essentially dextrose, maltose, dextrins and "starch intermediate products"; contains vitamins B and G in substantial quantities; packed in tins.

Manufacture.—A mixture of dextrose (65 per cent) and Vitavose (35 per cent). See this section for Vitavose (The Journal, Aug. 6, 1932, p. 477).

Analysis (submitted by manufacturer).—

	per cent
Moisture	1.5
Ash	1.5
Fat	0.0
Soluble protein (albuminoid N × 6.25)	2.7
Soluble amino and other nitrogenous compounds (amino N × 6.25)	2.3
Dextrose *	65.
Reducing sugars as maltose *	15.
Dextrins *	12.
Crude fiber	0.0
Total carbohydrates (by difference)	87.
Iron (Fe)	0.004

* Estimated from analysis of Vitavose and from factory formula.

Calorics.—3.9 per gram; 111 per ounce.

Vitamins.—Vitamin assay shows a content of vitamins B and G at least equal to 30 times and 10 times, respectively, of that of equal weights of fresh raw whole milk.

Claims of Manufacturer.—Intended particularly for the carbohydrate, and vitamins B and G supplement of milk for infants. May be used as a similar diet supplement for children and adults.

HECHT'S KEW BEE BREAD
HECHT'S SLICED BREAD

Manufacturer.—Hecht's Bakery, Bristol, Tenn.

Description.—A white bread made by the sponge dough method (method described in The Journal, March 5, 1932, p. 817); prepared from a mixture of patent flours, water, shortening, yeast, salt, dextrose, shortening, evaporated milk and a yeast food containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate.

Analysis (submitted by manufacturer).—

	per cent
Moisture (entire loaf)	36.8
Ash	1.7
Fat	3.0
Protein (N × 6.25)	9.5
Crude fiber	0.3
Carbohydrates other than crude fiber (by difference)	48.7

Calorics.—2.6 per gram; 74 per ounce.

Claims of Manufacturer.—A bread of good quality.

[2] Schaudinn's fluid: Two parts of saturated aqueous mercuric chloride in physiologic solution of sodium chloride, one part 95 per cent alcohol. This is the stock solution and will keep indefinitely. Four cc. of glacial acetic acid is added to 96 cc. of the stock solution on using. Fresh solution should be made up at frequent intervals.

VI-ZOY

(Essentially Sugars, Cocoa, Soy Bean Flour, Fats, Dry Yeast, Salts, Cod Liver Oil and Cod Liver Oil Concentrate, and Flavoring; Contains Vitamins A, B, D and G)

Manufacturer.—Harshaw Essential Foods, Inc., Cleveland.

Description.—A powdered food for the preparation of a nutritious beverage, contains sucrose, soy bean flour, cocoa, lactose, maltose, dextrose, dried yeast, butter, coconut and cottonseed oils, cod liver oil and cod liver oil concentrate calcium, iron and magnesium lactate, potassium and sodium chlorides, coumarin, vanillin and other flavoring, contains vitamins A, B, D and G.

Manufacture.—Dried soy beans are freed of foreign materials, washed, treated with dilute acid solution, washed free of acid, steamed, ground, and dispersed in water to a milky fluid. The fats and cod liver oil concentrate are added, and the mixture is homogenized and spray dried in hot air currents (from 85 to 90 C.). The powder is promptly cooled, is mixed with the sugars, cocoa, salts and flavors, is bolted through a sixty mesh screen, and is packed in hermetically sealed cans from which the air is withdrawn under vacuum and replaced by nitrogen gas to prevent the development of rancidity.

Analysis (submitted by manufacturer).—

	per cent
Moisture	2.1
Ash	3.2
Fat (ether extract)	11.6
Protein (noncaffeine and nontheobromine N × 6.25)	13.7
Reducing sugars as dextrose	10.7
Sucrose (copper reduction method)	41.0
Starch (acid hydrolysis method)	2.9
Crude fiber	2.0
Total carbohydrates other than crude fiber (by difference)	67.0
Caffeine	0.04
Theobromine	0.32
Phosphorus (P)	0.31
Calcium (Ca)	0.30
Iron (Fe)	0.02

Calories.—4.3 per gram, 122 per ounce.

Vitamins.—Biologic tests by means of rats give the following vitamin content:

Vitamin A: 280 units per ounce. (One unit is the minimum amount of the substance required daily to give an average gain in weight of 3 Gm. a week for eight weeks after the "depletion" period.)

Vitamin B complex: 28 units per ounce. (One unit of Vitamin B "complex" is the minimum amount of test substance required daily to induce an average gain of 3 Gm. a week for eight weeks after the depletion period.)

Vitamin D: 35 Steenbock units (curative method) per ounce. (One Steenbock unit [curative method] is the total amount of substance required to induce a positive line test in ten days.)

Claims of Manufacturer.—A powdered food for the preparation of a table beverage with milk, for food tablets, etc. Enhances or supplements the vitamins A, B, D and G values, iron and calcium content, and caloric value of milk. Vi-Zoy attractively flavors milk.

EHMANN RIPE OLIVES

(Medium, Large, Extra Large, Mammoth, Giant, Jumbo, Colossal)

Manufacturer.—Ehmann Olive Company, Oroville, Calif.

Description.—California ripe olives of graded sizes in brine.

Manufacture.—The fresh mature fruit is mechanically separated into olives of definite sizes; these are separately placed in processing vats containing a dilute solution of caustic soda (2 per cent) within a few hours after harvesting. The alkaline solution removes natural bitter elements (tannic acid); from four to seven applications of the alkaline solution, depending on the size of the olives, are necessary to penetrate entirely to the olive pit. Usually there is a lapse of from five to seven days between the alkaline treatments. The olives remain in the solution only a few hours each time and are washed three or four times daily with fresh water between the treatments. After the last caustic soda treatment the alkali is washed out with water and the olives are allowed to stand in salt brine. After sufficient salt flavor is acquired, they are given a final sorting and packed in brine (2.5 to 3 per cent) in tins and glass jars. The sealed packages are processed at 116 C. for one hour. The entire preparation and processing are under the supervision of the California State Department of Public Health.

Analysis (submitted by manufacturer).—

The edible portion of ripe olives is 81 per cent of the entire olive.

(edible portion of drained olives, sizes medium, large, extra large)

	per cent
Moisture	73.5
Ash	2.3
Fat	18.6
Protein (N × 6.25)	1.3
Crude fiber	1.8
Carbohydrates other than crude fiber (by difference)	2.5

(edible portion of drained olives, sizes giant, jumbo, colossal)

	per cent
Moisture	82.5
Ash	2.1
Fat	9.1
Protein (N × 6.25)	1.3
Crude fiber	2.6
Carbohydrates other than crude fiber (by difference)	2.4

Calories.—(Small sizes) 1.8 per gram, 51 per ounce.
(Large sizes) 1.0 per gram, 28 per ounce.

Claims of Manufacturer.—Ripe olives of graded sizes for table use.

DAVIDSON'S PRIZE WHEAT BREAD

(75% White Flour, 25% Whole Wheat Flour)

Manufacturer.—Davidson Baking Company, Portland, Ore.

Description.—A white bread made by the sponge dough method (method described in The Journal, March 5, 1932, p. 817), prepared from patent flour, whole wheat flour, water, sucrose, yeast, salt, shortening, molasses, malt syrup and a yeast food containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate.

Analysis (submitted by manufacturer).—

	per cent
Moisture (entire loaf)	35.5
Ash	0.9
Fat	1.2
Protein (N × 6.35)	10.0
Crude fiber	0.7
Carbohydrates other than crude fiber (by difference)	51.7

Calories.—2.2 per gram, 62 per ounce.

Claims of Manufacturer.—A bread of good quality.

CROWN CAKE FLOUR (Bleached)

Manufacturer.—Crown Mills, Portland, Ore.

Description.—A soft white wheat short patent flour designed for cake baking.

Manufacture.—Selected soft white wheat is cleaned, washed, tempered, and milled by essentially the same procedures as described in The Journal, June 18, 1932, page 2210. Chosen flour streams are blended, bleached with 21 Gm. of chlorine for each 196 pounds and 1 part of benzoyl peroxide to 28,000 parts of flour and automatically packed in bags.

Analysis (submitted by manufacturer).—

	per cent
Moisture	13.0
Ash	0.36
Fat (ether extraction method)	1.0
Protein (N × 5.7)	8.7
Crude fiber	0.3
Carbohydrates other than crude fiber (by difference)	76.6

Calories.—3.5 per gram, 99 per ounce.

Claims of Manufacturer.—A soft white wheat short patent flour designed for cake baking.

USEMORE BRAND GOLDEN SYRUP

(85 Per Cent Corn Syrup, 15 Per Cent Refiners' Syrup)

Packer.—D. B. Scully Syrup Company, Chicago.

Distributor.—Service Grocer Company, Detroit.

Description.—A table syrup, a corn syrup flavored with refiners' syrup.

Manufacture, Analysis, Calories, Claims of Manufacturer.—See these sections for Banner Blue Corn Syrup with Cane Flavor (The Journal, March 5, 1932, p. 817).

MEDICAL EDUCATION IN THE UNITED STATES AND CANADA

ANNUAL PRESENTATION OF EDUCATIONAL DATA FOR 1931-1932 BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

PART I. PREMEDICAL EDUCATION

For the convenience of admission officers of medical schools, the Council on Medical Education and Hospitals has, since 1915, published a list of "Approved Colleges of Arts and Sciences and Junior Colleges," which is a consolidation of the approved lists of recognized national and regional standardizing agencies. The same information is also contained in Bulletin 19, together with Supplements 1 and 2, issued by the Office of Education in the United States Department of the Interior.

Prospective medical students do well to secure their premedical training in colleges which are included in the approved list. Otherwise they may find it difficult or impossible to enter the medical school of their choice; for, while there is no inviolable rule excluding candidates from unaccredited colleges, the medical schools, in selecting from a large number of applicants, naturally and properly give the preference to those whose preparation has been received in institutions which are known to conform to accepted standards or exact of students from other institutions, qualitatively and quantitatively, a higher performance. Colleges not named in the accompanying list are urged to apply for approval to one of the organizations appearing in the key to table 1.

Junior Colleges.—Credentials of premedical work taken in junior colleges (indicated in the list by an asterisk) must show the completion of at least sixty semester hours in subjects of college grade, including the required credits in physics, chemistry, biology and English. Students presenting such credentials must have completed fifteen units of accredited high school work before taking college courses.

Normal Schools.—Students presenting credentials from normal schools, which are organized primarily for the training of teachers, may be accepted if such credentials have the certification of the registrar of the state university that the courses completed by the student are the equivalent of the courses accepted from accredited colleges and universities.

Table 1.—*Approved Colleges of Arts and Sciences and Junior Colleges*

Minimum Standard of Education Preliminary to the Study of Medicine

Revised to September, 1931

The minimum requirement for admission to an approved medical college is a four-year high school education or its full equivalent and sixty semester hours of collegiate work, exclusive of military and physical education, extending through two years, of thirty-two weeks each, exclusive of holidays, in an accredited college. The subjects included in the two years of college work, should be in accordance with the following schedule.

(*a*) *Chemistry.*—Twelve semester hours required of which at least eight semester hours must be in general inorganic chemistry, including four semester hours of laboratory work and four semester hours in organic chemistry, including two semester hours of laboratory work. In the interpretation of this rule, work in qualitative analysis may be counted as general inorganic chemistry.

SCHEDULE OF SUBJECTS OF THE TWO YEAR PREMEDICAL COLLEGE COURSE

Sixty Semester Hours † Required

Required Subjects:	Semester Hours
Chemistry (a)	12
Physics (b)	8
Biology (c)	8
English composition and literature (d)	6
Other nonscience subjects (e)	12
Subjects Strongly Urged:	**Semester Hours**
A modern foreign language (f)	6-12
Advanced botany or advanced zoology	3-6
Psychology and logic	3-6
Advanced mathematics, including algebra and trigonometry	3-6
Additional courses in chemistry	3-6
Other Suggested Electives:	
English (additional), economics, history, sociology, political science, mathematics, Latin, Greek, drawing.	

† A semester hour is the credit value of sixteen weeks' work consisting of one lecture or recitation period per week, each period to be not less than fifty minutes net, at least two hours of laboratory work to be considered as the equivalent of one lecture or recitation period.

(*b*) *Physics.*—Eight semester hours required, of which at least two must be laboratory work. It is urged that this course be preceded by a course in trigonometry.

(*c*) *Biology.*—Eight semester hours required, of which four must consist of laboratory work. This requirement may be satisfied by a course of eight semester hours in either general biology or zoology, or by courses of four semester hours each in zoology and botany, but not by botany alone.

(*d*) *English Composition and Literature.*—The usual introductory college course of six semester hours, or its equivalent, is required.

(*e*) *Nonscience Subjects.*—Of the sixty semester hours required as the measurement of two years of college work, at least eighteen, including the six semester hours of English, should be in subjects other than the physical, chemical or biologic sciences.

(*f*) *Foreign Language.*—A reading knowledge of a modern foreign language is strongly urged. If the reading knowledge of this language is obtained on the basis of high school work, the student is urged to take another language in his college course. It is not considered advisable, however, to spend more than twelve of the required sixty semester hours on foreign languages.

(*g*) *In General.*—This premedical course in both quantity and quality must be such as to make it acceptable as the equivalent of the first two years of the course leading to the degree of Bachelor of Science or Bachelor of Arts in approved colleges of arts and sciences.

A list of colleges of arts and sciences approved by the Council on Medical Education and Hospitals is revised and published in this issue. By an approved college (of arts and sciences) is meant one whose standing has been vouched for by some standardizing agency in whose methods the Council has confidence. Colleges of liberal arts and sciences which have been approved by their district association, or by the Association of American Universities, are considered as acceptable to the Council on Medical Education and Hospitals. Other colleges of known reputability may also be considered where the students present extra credits and exceptionally high grades.

Premedical college courses given in or by professional schools, by normal schools, or advance years taken in high schools, will not be considered as acceptable unless the student's credentials are certified by the registrar of the state university of the state in which the college is located, as the equivalent of the first two years of the course leading to the Bachelor of Arts or Science degree in colleges approved by the state university.

PART II. MEDICAL EDUCATION

Executive officers of medical colleges have contributed the reports on which the following statistics are based. Acknowledgment is here made of their splendid cooperation.

DEVELOPMENTS IN MEDICAL EDUCATION

In 1928, the Council on Medical Education and Hospitals discontinued the classification A, B and C, as applied to medical schools, listing them thereafter only as approved or unapproved. There has been some confusion since that time in the use of the terms "class A" and "approved," so that in view of the fact that the term "class A" was still being generally used, a ruling was passed in June, 1931, to the effect that

> The terms "class A" and "approved," when used in reference to medical colleges, shall be synonymous and may be used interchangeably.

The University of Mississippi School of Medicine still continues on a very uncertain basis, its approval being held in abeyance until the effect of recent changes can be determined. A new governor has been elected and a new board of control for the university created. The former chancellor, Dr. Alfred Hume, has been reappointed. In order, however, to balance the budget, the appropriation for the university has been materially reduced. What the effect on the medical school will be is not yet known.

STATISTICS OF MEDICAL COLLEGES

Table 2 gives the figures for the academic year 1931-1932 for the approved medical colleges in the United States shown by classes. The total number for the first year was 6,260, for the second year 5,462, third year 4,932, and fourth year 4,885, or, respectively, 196, 76, 148 and 123 fewer than last year. The total enrolment in the various medical colleges in the United States and Canada, as well as the number of graduates (men and women), graduates with baccalaureate degrees, teachers, tuition fees by classes, name of executive officer and the date of the beginning and ending of the session 1932-1933 is shown in table 7 on pages 738-739. The figures in this table in heavy type are the totals for each of the states. These are also shown collectively in table 3. New York, with the largest number of medical colleges, was the first in the number of medical students, having a total of 2,649; Pennsylvania was second with 2,401, and Illinois third with 2,240. There were 630 graduates in New York, 581 in Pennsylvania and 497 in Illinois.

* School operated on the quarter system, and students are not promoted by classes.

EVENTS OF THE YEAR

The University of Missouri School of Medicine, which last fall inaugurated clinical teaching and offered a third year program of instruction, has been compelled to defer the establishment of the fourth year of the curriculum. For the present, at least, it will continue to operate as a two year school.

The University of Southern California School of Medicine, by means of its affiliation with the Los Angeles County General Hospital, Unit No. 1, has been giving instruction to its third year class. The Council, at its meeting on May 8, 1932, voted

> That the course for the first two years as now given continue to receive the Council's approval and that the curriculum outlined for the third and fourth years be endorsed.

FIFTH YEAR MEDICAL STUDENTS

The fifteen medical colleges in the United States and Canada which require a fifth, or intern, year before the M.D. degree is conferred are listed in table 4, with the number of students enrolled in this year. There were 1,177 enrolled, as compared with 1,025 in United States schools only during 1930-1931. This year there were 1,067 fifth year students in United States schools.

1932	76	22,135	4,936

NUMBER OF MEDICAL COLLEGES AND STUDENTS

The total number of undergraduate medical students in the approved schools for the session 1931-1932 (table 5) was 22,135, an increase of 153 over last year. This is the largest number of students enrolled since 1905, when 26,147 students were in attendance at the 160 medical schools then existing. The increase of 153 students over the previous year, however, is less than one half of the increase noted in the corresponding gain in 1930.

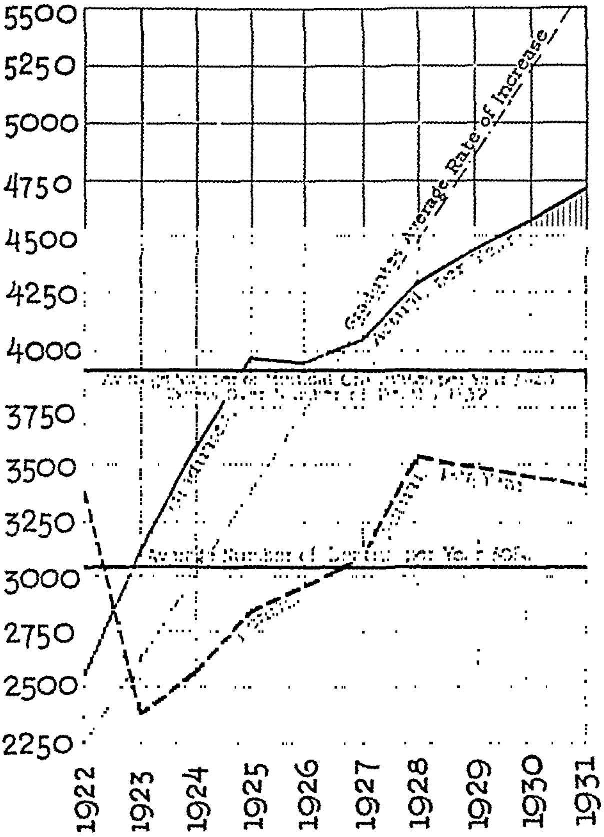

Chart 1.—Showing the increase in medical graduates and the number of deaths in the medical profession.

NUMBER OF MEDICAL GRADUATES

Since 1922 the number of medical graduates in the United States has steadily increased, as shown in chart 1. The number of graduates in 1932 exceeded those of 1931, and while the number of deaths in 1932 cannot be determined, it is believed that the graduates will represent about 50 per cent more than the loss by death in the medical profession each year.

TABLE 6.—*Women in Medicine*

Year	Women Students	Percentage of All Students	Women Graduates	Percentage of All Graduates
1905	1,073	4.1	219	4.0
1910	907	4.0	116	2.6
1915	592	4.0	92	2.6
1920	818	5.8	122	4.0
1925	910	5.0	204	5.1
1926	935	5.0	212	5.4
1927	964	4.9	189	4.7
1928	929	4.5	207	4.9
1929	925	4.4	214	4.8

* Gives only the first two years of the medical course

† The population for the following cities are Berkeley, 82,109, Loma Linda, 2,500, Bloomington, 18,227, Lawrence, 13,726, Ithaca, 20,708

[1] Hospital internship required for graduation See table 4 for the *fifth year registration*

[2] The following universities make an additional charge for non residents Arkansas, $100, California, $60, Colorado, $132, Georgia, $200 Illinois, $100, Indiana, $75 first year, $175 next three years, Iowa, $264, Kansas, $ 0 Maryland, $150 Michigan, $100 Detroit, $100, Minnesota, $25, Mississippi $50, Missouri, $30, North Carolina, $100 North Dakota, $90, Ohio State, $150, Cincinnati, $50 (nonresidents of Cincinnati), Oregon, $60, South Dakota, $50 Vermont, $75 (an *activity fee of $50 is charged all students not holding academic* degrees) Virginia, $20 Medical College of Virginia, $100, West Virginia, $250, and Wisconsin, $200

[3] For residents of the state the charge is reduced $ 0 each quarter

[4] Nonresident fee is $200

[5] See College Items for fifth and sixth year fees

[6] Effective September, 1932, the third year and the proposed fourth year will be discontinued

[7] The first two years as now given are approved and the curriculum outlined for the third and fourth years is endorsed

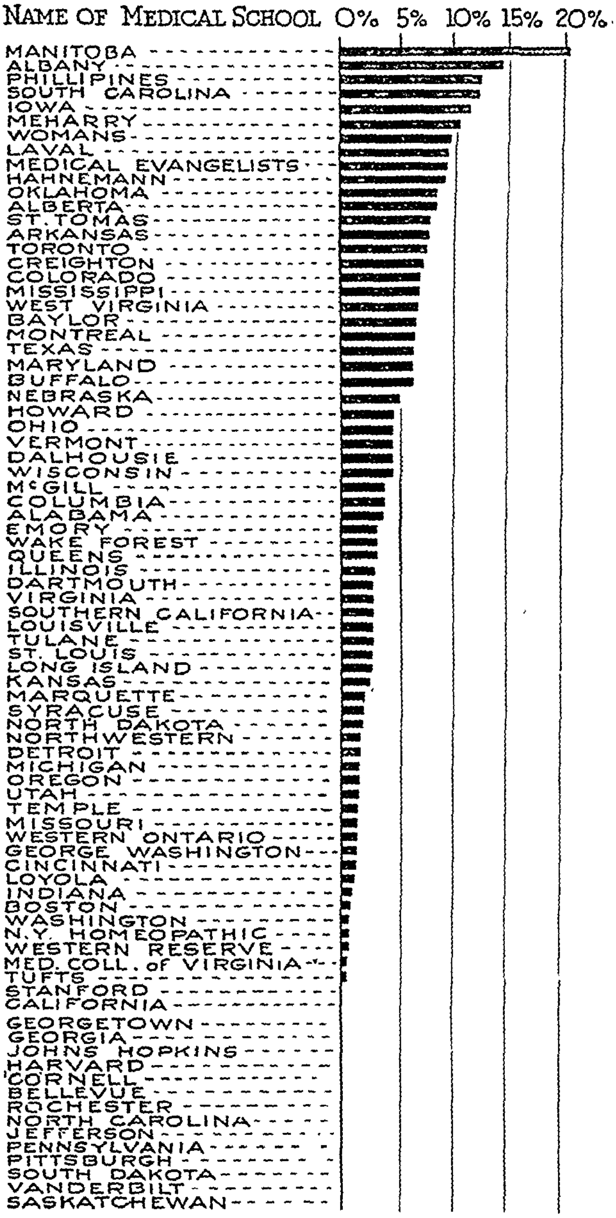
[8] Approval held in abeyance until the reorganization is complete

(Continued from page 737)

with 990 for the previous year, a decrease of 35. They constitute about 4 per cent of the total number of medical students. The number of women students has been quite constant for the past twenty years. There were 208 women graduates this year.

"REPEATERS" IN MEDICAL SCHOOLS

A preliminary report of the number of students being allowed to repeat courses in which they failed was published in The Journal last year.[1] The consolidation of the figures for the freshman year with those reported for the session of 1931-1932 was published in The



Average reported for 1930-1931 and 1931-1932
6 schools on the quarter system not included
7.3% above 10%
23.2% between 5% and 9.9%
50% between 0.1% and 4.9%
19.5% none

[1] J. A. M. A. **96**: 1498 (May 2) 1931; **97**: 623 (Aug. 29) 1931.

JOURNAL a few months ago [2] and are reproduced herewith in chart 2. Generally, it may be assumed that those schools which have a two year average of 5 per cent or less are maintaining reasonable academic standards. The percentage of classes repeating courses is shown by individual schools in table 8, referring to the session of 1931-1932. The greatest number of repeaters are, of course, students who have failed in their first year of medicine. Failures in the last two years are relatively few. There were no students repeating courses in seventeen schools, and sixteen schools had students repeating only in the first year.

Listed in table 9 are the number of students repeating courses in the schools operating under the quarter system.

NEGROES IN MEDICAL SCHOOLS

The Negro medical students for the session of 1931-1932 are recorded by classes in table 10. The total number of students and graduates for the year 1930-1931 is also shown for comparison. There were 497 Negro students enrolled in 1930-1931 and 479 during 1931-1932, a decrease of 18.

MEDICAL SCHOOL FEES

Reference is directed to table 7, in which fees charged by each medical college are recorded. In table 11, these figures have been collected to show the number of schools in various fee groups. Every college in the United States except one charging $200 or under is a state university, and three of these have fees for residents less than $100. Most state universities, however, require an additional fee of nonresidents, as is indicated in footnote 2, table 7.

STUDENTS FROM THE UNITED STATES IN OTHER SCHOOLS

The migration of medical students to European and Canadian medical schools is continuing with increasing numbers, as shown in table 12. The figures for 1931-

* Name of medical school not known.

1932 have increased 50 per cent over those for 1930-1931. The distribution of these students has, however, somewhat changed, as indicated in the following table, which includes the six countries having the largest enrolment:

	1930-1931	1931-1932	Increase or Decrease
Great Britain	322	339	....
Canada	300	308	....
Austria	114	188	+50%
Italy	78	155	+100%
Germany	72	183	+150%
Switzerland	65	214	+230%

Doubtless one factor in the increase shown by the continental universities has been the active solicitation carried on by the Hamburg American Steamship Company. Letters received from correspondents abroad would seem to indicate that, in some cases at least, the educational standards for these migrating students are less rigid than those prevailing in this country.

RECORDS OF FOREIGN GRADUATES IN STATE LICENSING EXAMINATIONS

In table 13 is shown the record in licensing examinations of the graduates of medical schools other than those of the United States and Canada from which, within five years, five or more graduates have appeared before the various state boards of this country. The

Number of schools with 26-50 per cent failures	25
Number of schools with 51-100 per cent failures	24
Total number of schools	56

number of candidates is 984; of schools represented, 56. Two schools with 30 graduates examined have had no failures. Forty-nine schools with 888 graduates have had more than 25 per cent failures. In this country no school would be approved which had so large a percentage of failures among its graduates and it may fairly be questioned whether state examining boards can reconcile their obligations to the citizens of their own states with the policy of admitting to the licensing examination the graduates of schools which have consistently been characterized by a large percentage of failures.

PART III. EDUCATION OF INTERNS IN APPROVED HOSPITALS

The active coöperation of all hospitals approved for internships has again enabled the Council on Medical Education and Hospitals to present statistics concerning intern education. A total of 676 replies was received in time for tabulation on the special blank provided the hospitals for the purpose of reporting the present status of their educational programs. To date all but *two of the 696 hospitals approved for interns* have reported. The returns were highly satisfactory and greatly appreciated.

MEDICAL GRADUATES AND INTERNSHIPS

In table 14 is shown the number of graduates of 1931 and fifth year students who have served or are serving internships. With the exception of one in the United States and two in Canada, every school in the list has more than 90 per cent of its graduates serving internships. Excluding those schools that require the internship for graduation, 95.5 per cent of all graduates here listed have this added experience. In view of the fact that only one third of the states make it obligatory, this seems to be a remarkable showing.

The year 1931 was not an easy one for hospitals. It is gratifying to note that in the face of quite general adverse circumstances no notable regressions have occurred with respect to intern training. The hospital has seemingly entrenched itself more firmly than ever as a potent factor in medical education.

Table 15 indicates that intern service has been eminently satisfactory. More positions are offered, the number of approved hospitals has increased, and the hiatus existing between the candidates and the number of positions is greater than ever before. As pointed out in the Hospital Number of THE JOURNAL, June 11, there is at present no dearth of applicants for house positions in the hospitals because many interns are deterred from the establishment of a practice until more favorable times. These present tendencies have brought the conviction that, of the several plans now considered toward bridging the gap between the number of medical graduates and the intern positions, the most feasible is the practice of using the same intern over longer periods of time. It may readily be seen that if the present almost universal twelve months service were extended to fifteen or eighteen months, a far greater spread of interns would occur. Another idea that is spreading slowly throughout the hospital world is the practice of contracting for intern services at different times during the year, so that there always will be a few experienced interns in whom confidence can be placed while the new group is becoming accustomed to new duties and hospital methods.

* An internship or other acceptable clinical work is a requirement for graduation.

It is now considered axiomatic that the greater the cooperation of the staff the better the internship. In this survey an effort was made to learn which were the commonly accepted staff activities for interns and how generally they were carried into effect.

THE INTERN COMMITTEE

Intern committees represent the recognition on the part of hospital staffs that intern affairs need supervision and that the staff as a whole is too unwieldy a body to serve effectively. As a matter of fact, the intern committee itself does not serve very effectively yet it represents an advance over the older unsupervised methods of intern training.

As usually constituted, intern committees consist of three or four staff members, ordinarily appointed by the chief or president of the staff. Their duties (only occasionally mentioned in the by-laws) consist largely in making contact with students at the medical colleges, deliberating over applications, officially appointing interns, and approving schedules and regulations. The administration of disciplinary measures involved in infractions of hospital rules by the intern corps also devolves on the intern committee.

Table 15.—*Growth of Internships*

	1914	1920	1925	1930	1931
Number of approved hospitals	603	593	528	654	674
Medical graduates	3,594	3,047	3,974	4,565	4,735
Number of internships offered	3,095	3,420	3,832	5,531	6,154

This committee as it now exists represents a useful method of controlling the mechanics of internships. It leaves much to be desired from the point of view of controlling the actual service which the intern gives and the experience which he receives. In only a few hospitals are attempts made to stimulate the other staff members toward assuming a more active attitude regarding the training of interns. In still fewer instances are appraisals made which seek to evaluate the status of the educational program—to check improper tendencies or to supply forms of experience which all interns need and which require effort on the part of many hospitals.

It seems certain, however, that the intern committee is the anlage of the future organization of hospitals as teaching institutions. The present paucity of intern supply shows none but transitory signs of abating, and it would appear that hospitals must offer greater opportunities to attract the available candidates. It is not so much a question of giving interns greater license in the care of patients. Development should come in the direction of more rather than less supervision, in demands for more thorough case study, more sound teaching by qualified staff members rather than the assimilation of a hundred conflicting views on patient care expressed by as many individualistic visiting physicians. Some control of these efforts must be established and one can foresee the gradual assumption on the part of the intern committee of a greater and a much more intimate grasp on the details of intern instruction.

Table 16.—*Autopsy Performance in Approved Hospitals*

Percentage	Number of Hospitals			
	1926	1928	1930	1931
Over 70	14	16	19	24
50 to 70	21	45	56	62
30 to 50	68	132	164	210
15 to 30	146	249	354	295
Under 15	329	189	71	73*

* Twelve not reporting.

The ground work is already prepared in all but 15 of the 676 tabulated hospitals. The replies indicate that the membership of these intern committees is preponderantly medical. There were eighty nonmedical names listed as members, almost entirely made up of lay superintendents whose administrative function often makes it desirable for them to occupy such a position. In all, 125 superintendents were committee members.

It was learned that intern committees meet regularly in 374 hospitals and irregularly or not at all in 302 In response to the question "What steps does the intern committee take to insure good internships?" a great variety of answers was received. Some interpreted the question in the light of steps taken by the hospital to assure itself of a good well qualified intern. Others answered as was more nearly the intention; that is, the steps taken by the intern committee, to regulate the actual service which the intern receives in the hospital.

STAFF ACTIVITIES FOR THE INTERN

The accompanying table presents the reported facts concerning the activities of staffs toward the intern. Staff members fall into three main groups with regard to their reactions to interns. One group is made up of true teachers who either by predilection or by inclination assume the principal burden of instructing the interns Because of their interest, they receive the respect and loyalty of the house staff and it seems unnecessary to say that their patients usually receive the best care. Opposed to this small segment of the staff is a reactionary group which resents the intervention of interns in the care of their patients, and which, far from attempting to teach, assumes an entirely antagonistic attitude It is their feeling that interns as a class are unresponsive to training, especially to that which might come from associating with others more experienced than themselves.

Midway between these two lies another group which is by far the most numerous. Its members respond to the stimulus of fresh ideas of the interns, recognizing in this system a not unimportant means for new knowledge to diffuse itself through the profession from the medical centers They display a most wholesome cooperation toward increasing the experience of the young physicians.

The intern thrust into this milieu of conflicting opinions and points of view is obliged often to exert the most vigorous tenacity in adhering to the methods taught in his medical school. Too frequently he loses some of his idealism in consideration of the inadequacies he encounters. More important, however, is the fact that nothing can efface the imprint of those few compelling personalities who have guided his first faltering footsteps and whose example must affect permanently all his contacts with future patients.

TABLE 17.—*Staff Activities for Interns*

	Yes	No
Intern committees	661	15
Separate clinical pathologic conferences	431	245
Presence at monthly meetings	618	58
Ward rounds	645	31
Staff lectures	460	216
Record conferences	490	186
Departmental conferences	378	298
Journal clubs	83	593

Ward rounds and required presence at the regular monthly meetings are almost universally practiced in these 676 approved hospitals. They are the oldest and possibly the best methods of intern instruction yet devised and at the same time least taxing on the time and energy of the staff members. Bedside teaching and case discussion will probably never be supplanted as a most effective teaching plan. Many conferences as now conducted are of a clinical pathologic type. Four hundred and thirty-one hospitals report that such meetings are held as separate staff functions distinct from the regular monthly meeting. The manner and frequency of presentation differ in hospitals The pathologist is the principal factor in conducting the conferences in 337 hospitals In 294 hospitals, presumably they are conducted by the staff alone As to frequency, the presentations vary from monthly to daily. Some report the plan of holding conferences at each necropsy No one can estimate the benefit that emanates from these conferences, but they are now considered as the best single staff endeavor yet developed.

TABLE 18—*Various Duties Required of Interns*

	1930		1931	
	Yes	No	Yes	No
Presence at necropsies	613	501	581	95
Laboratory service	598	66	485	191
Roentgen ray service	537	127	580	96
Preparation of papers	398	266	460	216
Assigned readings	153	511	225	451
Dispensary service	418	246	449	247

Table 16 indicates the increasing number of hospitals which are moving up into the higher percentage figures of necropsy performance Insistence on adequate pathologic supervision has made possible notable advances. Three hundred and twenty-four hospitals report full time pathologists In 628 hospitals a pathologist is said to perform the necropsies, assisted by, or under the observation of, the interns, and 235 of these pathologists are approved as qualified specialists in their field by this council

Likewise the roentgenologist is frequently called on to teach interns either in his department or at the staff conferences. In 580 of these hospitals the interns receive some training in the department In 239 hospitals there are full time roentgenologists Many serve more than one hospital, so that 418 institutions have the services of men recognized as specialists in radiology by the Council on Medical Education and Hospitals.

The activities of the staff do not stop here As the table shows, in 460 hospitals lectures are given to the interns. The customary method is for the interns to choose the subject and the speaker. In this way the interns obtain advice and accurate information on subjects concerning which they themselves most definitely feel a need Frequently the subject matter of the lectures escapes from the province of scientific or clinical medicine into the fields of the economic and social aspects of medicine.

One reason for the great popularity of interns is the help which they give in keeping hospital records in acceptable form. In fact, there is good reason to believe that if the intern did not provide that service he would be *persona non grata* in most hospitals. History writing under such circumstances—namely, the setting down of observations on every new case admitted to the service, often ten to fifteen or more a day, is not the best plan for the hospital or the intern. The hospital gets slipshod and hastily prepared charts, and the intern develops that acute distaste for record keeping which characterizes so many present-day physicians.

Yet history taking should be an important and essential part of intern training. As now carried out in most hospitals, it has not been particularly educational but is becoming more so. In 490 hospitals, methods have been devised for teaching in connection with record keeping, together with criticisms and appraisals by staff members. Record conferences are held for the discussion of diagnostic conclusions arrived at from the history alone. At these conferences, deficiencies are also noted and improper tendencies on the part of the intern curbed.

So far, journal clubs have not gained much headway. Most approved hospitals have a library of some sort with reference texts and a selection of journals. The use of this material is desultory and unsustained. In only eighty-three hospitals does the intern benefit by reviews of the literature as presented in these clubs.

The use of the libraries, however, is stimulated in other ways. In many hospitals, interns prepare papers for presentation either before the intern staff or before the hospital staff. In more and more hospitals, definite reading assignments are being made and presumably the intern reports the results of his studies. The upkeep of the library is often a staff duty and is supported by a staff levy.

RESIDENTS IN INTERNSHIP HOSPITALS

This council has never, contrary to existing belief, required residents in internship hospitals. It is true that the presence of residents leads to better internships, or at least internships on a sounder educational basis. A resident accepts responsibility seriously, and his supervision of interns is in most instances more conscientious and certainly more constant than could be exerted by a staff member.

Interns themselves are averse to residents only as they represent a limitation of opportunity in the delivery or operating rooms. While it is only reasonable to feel that his efforts in working up a surgical case should be rewarded by an active participation in the treatment, the intervention of a resident ought not to be considered a slight or injury to the intern. The larger view of improvement in surgical practice must be taken, and it would seem that stricter regulation of surgical services for interns in hospitals would have such a tendency. More attention should be paid to diagnosis and postoperative care, to the treatment of fractures and first aid care of emergency cases as the most likely surgical conditions encountered by a young physician and for the care of which his hospital experience should primarily tend to fit him

STATE REQUIREMENTS OF PRELIMINARY EDUCATION

There are now forty-three states (counting Alaska and the District of Columbia) which, either by law, board ruling, or both, have adopted requirements of preliminary education in addition to a standard four-year high school education. Of these, thirty-nine require the two-year standard. Before 1908, not one state had any such requirement. One state has no definite requirement of preliminary education, while six states still require only a high school education. It is interesting to note also that seventeen states now require the completion of a year's internship in a hospital before the candidate is qualified to take the professional examination. All such requirements also have been adopted since 1909.

The states, the number of college years required and the time the higher requirements became or become effective are as follows:

	One Year of College Work		Two Years of College Work		A Hospital Internship

HOSPITAL INTERNSHIP REQUIRED BY MEDICAL COLLEGES

Fourteen medical colleges in the United States and three in Canada have adopted the requirement of a fifth year to be spent by the student as an intern in an approved hospital or in other acceptable clinical work before the M.D. degree will be granted These colleges and the years when the requirement became effective for matriculants and graduates are as follows:

UNITED STATES

	Affects Matriculants	Affects Graduates
University of Minnesota Medical School	1910 11	1915

NOTES

Information regarding acceptable internships in Canadian Hospitals may be obtained from the Canadian Medical Association, 184 College Street, Toronto, G Harvey Agnew, M D, Secretary, Department of Hospital Service

1 Women interns admitted
2 Women interns only
(a) $50 per month, bonus of $60 No maintenance
(b) Salary established by Government Pay Tables according to rank and service
(c) In lieu of maintenance
(d) Bonus of $110
(e) Bonus of $10 for satisfactory records
(f) Bonus of $150
(g) Bonus of $300
(h) Bonus of $100
(i) $10 a month for first 6 months $20 a month for next 6 months, $30 a month for last 6 months, bonus of $50
(j) Bonus of $120
(k) Bonus of $180
(m) Bonus of $50
(n) Bonus of $125
(o) Bonus of $60
(p) Bonus of $40
(q) Bonus of $200
(r) Bonus of $160
(s) Bonus of $240
(1 a) January, April, July, August and November
(1 b) Quarterly
(1 c) January, March, July, September and November
(1 d) March, July and November
(1 e) January, July and October
(1 f) April, July and October
(1 g) July, August and September
(1 h) January, May and September
(1 i) Every two months
(1 j) Every six weeks
(1 k) January, March, May, July, September and November
(1 m) February, June and October
(1 n) January, June and September
(1 o) June, October and December
(1 p) June, July and August
(1 q) July, September and October
(1 r) April, June and August
(1 s) May July and October
(1 t) All internships reserved for the fifth year students of the College of Medicine, University of the Philippines
(1 u) January, April and July

University of Georgia Medical Department University *Place*—Organized in 1828 as the Medical Academy of Georgia the name being changed to the Medical College of Georgia in 1829 Since 1873 it has been *known* as the *Medical Department* of the University of Georgia Property transferred to university in 1911 Classes were graduated in 1833 and all subsequent years except 1862 and 1863 Coeducation was begun in 1920 The faculty includes 35 professors and 30 assistants 65 in all Two years of college work is required for entrance The course is four years of thirty four weeks each The fees for each of the four years, respectively, are $105, $100, $100 and $100 for residents of Georgia and $300 each year for nonresidents The total registration for 1931 1932 was 154, graduates, 40 The one hundred and fourth session begins Sept 24, 1932, and ends June 5, 1933 The Dean is William Lorenzo Moss, M D

ILLINOIS

Chicago

Loyola University School of Medicine, 706 South Lincoln Street —Organized in 1868 as the Bennett College of Eclectic Medicine and Surgery Eclecticism dropped and title of Bennett Medical College assumed in 1909 First class graduated in 1870, and a class graduated each subsequent year Absorbed the Illinois Medical College in 1910 and the Reliance Medical College in 1911 In 1910 it became by affiliation the School of Medicine of Loyola University, the university assumed full control in 1915 Took over by purchase the Chicago College of Medicine and Surgery in 1917 Coeducational Two years of college work is required for admission The course of study is five years, including an internship in a hospital The faculty is composed of 50 *professors and 212* assistants, *lecturers, instructors* and *others,* a *total* of 262 The fees for each year are $363 50 $377 50, $332 and $298, respectively The total enrolment for 1931 1932 was 500 graduates, 113 The next session begins Oct 3, 1932, and ends June 10, 1933 The Dean is Louis D. Moorhead, M D

Northwestern University Medical School, 303 East Chicago Avenue—Organized in 1859 as the Medical Department of Lind University First class graduated in 1860 In 1864 it became independent as the Chicago Medical College It united with Northwestern University in 1869 but retained the name of Chicago Medical College until 1891, when the present title was taken Became an integral part of Northwestern University in 1905 Coeducational since 1926 The faculty comprises 119 professors and 283 lecturers and assistants, a total of 402 The requirements for admission are such as will admit to the College of Liberal Arts of Northwestern University, plus three years of college work, including courses in physics, chemistry, biology and a modern language The course covers four years of eight months each and a fifth year spent in an approved hospital as an intern or in other practical work The total fees are $355 each year The total registration for 1931 1932 was 555, graduates, 116 The seventy fourth session begins Oct 4, 1932, and ends June 12, 1933 The Dean is Irving S Cutter, M D

University of Chicago, Rush Medical College, 1758 West Harrison Street—Chartered in 1837, held first class in 1843 First class graduated in 1844 In 1887 the college became the medical department of Lake Forest University, retaining however, its self government This *relation* was dissolved in *April, 1898,* and in the same *month affiliation* with the University of Chicago was established Since that time the work of the first two years has been given on the University Quadrangles In May, 1924, by a new contract, the University of Chicago took over the work of Rush Medical College as a department of the university Since 1914 the course has included a fifth year consisting of a hospital internship or of a fellowship in one of the departments Coeducational since 1898 Classes are limited to 140 students No application for admission is accepted after June 1 The school operates under the 'quarter system" in which the year is divided into four quarters of twelve weeks each, the completion of the work of three of these quarters gives credit for a college year The faculty is composed of 126 professors, 148 associates, instructors and others, a total of 274 The fee for the third year is $380, and for the fourth $400 Total registration for 1931 1932 was 307, graduates, 154 The eighty eighth session begins Oct *3, 1932, and ends June 13, 1933* The school *is in session* all year except the month of September The Dean is Ernest E Irons, M D

University of Chicago, School of Medicine of the Division of the Biological Sciences, Fifty Eighth Street and Ellis Avenue—*Organized in 1924 as a part of the Ogden Graduate School of Science* The work of the first two years of the medical course has been given on the Quadrangles since 1899, and that of the clinical years was added in 1924 with the organization of this medical school All the work leading to the degree of M D may now be done on the Quadrangles A fifth year, spent in successful internship in an approved hospital or in advanced work in some branch of medical science, is required for graduation Coeducational The faculty is composed of 95 professors, 135 associates, instructors and others a total of 230 The requirements for admission are three years of college work including courses in college chemistry, physics and biology, and a reading knowledge of German or French The school operates under the quarter system," in which the year is divided into four quarters of twelve weeks each, the completion of the work of three of these quarters gives credit for a college year Students are admitted at the beginning of either autumn or spring quarters Applications for admission in the autumn should be made in April for admission in the spring, in January The tuition fees for each of the four years are $375 Total registration for 1931 1932 was *289* graduates, 19 The next session begins Oct 3, 1932, and ends June 14, 1933 The Dean of Medical Students is B C H Harvey, M D

University of Illinois College of Medicine 1853 West Polk Street—Organized in 1882 as the College of Physicians and Surgeons *The first class* graduated in *1883* It became the Medical Department of *the University of Illinois* by *affiliation* in *1897 Relationship* with the university was canceled in June 1912, and was restored in March, 1913, when the present title was assumed Coeducational since 1898 Two years of collegiate work is required for admission The curriculum covers four years of thirty two weeks each, and a year of internship in an approved hospital The faculty is composed of 92 professors and 209 assistants and instructors, a total of 301 The tuition is $200 a year for students who are residents of Illinois $300 a year for non resident students The total registration for 1931 1932 was 589, graduates 95 The fifty first session begins Oct 3, 1932, and ends June 9, 1933 The Dean is David John Davis, M D

INDIANA

Bloomington-Indianapolis

Indiana University School of Medicine—Organized in 1903 but did *not give all the work of the first two years of the medical course* until 1905 In 1907, by union with the State College of Physicians and Surgeons, the complete course in medicine was offered In 1908 the Indiana Medical College, which was formed in 1905 by the merger of the Medical College of Indiana (organized in 1878), the Central College of Physicians and Surgeons (organized in 1879), and the Fort Wayne College of Medicine (organized in 1879) merged into it The first class was graduated in 1908 Coeducational since organization The faculty consists of 231 professors, lecturers, associates and assistants Two years of *collegiate* work *is required for admission The* work *of the* first year is done at Bloomington The work of the other three years is given at Indianapolis The fees for each of the four years, respectively, are $187, $186, $182 and $177 for residents of Indiana, and $75 additional for first year, and $175 additional for last three years, for nonresidents A fifth optional intern year leading to the "M D cum laude' has been added The total registration for 1931 1932 was 430, graduates 94 The next session begins Sept 13, 1932 and ends June 12, 1933 The Dean at Bloomington is B D Myers, M D, and the Dean at Indianapolis is W D *Gatch,* M D

IOWA

Iowa City

State University of Iowa College of Medicine, University Campus—Organized in 1869 First session began in 1870 First class graduated in 1871 Absorbed Drake University College of Medicine in 1913 Coeducational since 1870 The faculty is made up of 46 professors, 63 lecturers, demonstrators and assistants, a total of 109 Two years of college work, including courses in physics, chemistry, biology, German and English, is required for admission The course of study covers four years of thirty four weeks each The tuition fee is $192 each year for residents of Iowa and $456 for nonresidents Total registration for 1931 1932 was 379, graduates 99 The sixty third session begins Sept 26, 1932, and ends June 5, 1933 The Dean is Henry Spencer Houghton, M D

KANSAS

Lawrence-Kansas City

University of Kansas School of Medicine—Organized in 1880 It offered only the first two years of the medical course until 1905, when it merged with the Kansas City (Mo) Medical College, founded in 1869, the College of Physicians and Surgeons, founded in 1894, and the Medico Chirurgical College, founded in 1897 Absorbed Kansas Medical *College* in 1913 *First class graduated* in *1906 The clinical* courses are given at Kansas City Coeducational since 1880 The faculty includes 23 professors and 137 instructors, assistants and others, a total of 160 The requirement for admission is two years of collegiate work The course covers four years of nine months each The total fees for residents of the state for each of the four years are, respectively, $162, $154, $155 and $159 For nonresidents the fees are $50 additional each year The total registration for 1931-1932 was 254, graduates, 53 The fifty third session begins Sept 22, 1932, and ends June 12, *1933* The *Dean* is *H R* Wahl, M D, Kansas City

KENTUCKY

Louisville

University of Louisville School of Medicine, First and Chestnut streets.—Organized in 1837 as Louisville Medical Institute. The first class graduated in 1838, and a class graduated each subsequent year except 1863. In 1846 the name was changed to University of Louisville Medical Department. In 1907 it absorbed the Kentucky University Medical Department; in 1908, the Louisville Medical College, the Hospital College of Medicine and the Kentucky School of Medicine. In 1922 it changed its name to the University of Louisville School of Medicine. Coeducational since organization. Two years of college work is required for admission. The faculty numbers 27 professors and 116 assistants, instructors and others, a total of 143. Students limited to 90 freshmen, 90 juniors; number of sophomores and seniors contingent on number promoted. Course covers four years of thirty-two weeks each, exclusive of vacations and examinations. Fees for four years are, respectively, $365, $365, $370 and $380. Total registration for 1931-1932 was 340; graduates, 88. Next session begins Sept. 15, 1932, and ends June 3, 1933. The Dean is John Walker Moore, M D.

LOUISIANA

New Orleans

Tulane University of Louisiana School of Medicine, 1430 Tulane Avenue.—Organized in 1834 as the Medical College of Louisiana. Classes were graduated in 1835 and in all subsequent years except 1863-1865, inclusive. It was transferred to the Medical Department of the University of Louisiana in 1847, and became the Medical Department of the Tulane University of Louisiana in 1884. Present title in 1913. Coeducational since 1915. The faculty comprises 30 professors and 127 associate and assistant professors, instructors and assistants, a total of 157. The course covers four years of thirty-two weeks each. Two years of collegiate work is required for admission. Total fees for each of the four years, respectively, are $350, $340, $325 and $355. The total registration for 1931-1932 was 483; graduates, 108. The ninety-ninth session begins Sept. 26, 1932, and ends June 7, 1933. The Dean is Charles Cassedy Bass, M.D.

MARYLAND

Baltimore

Johns Hopkins University School of Medicine, Washington and Monument streets.—Organized in 1887. Offered preliminary course only until 1893. The first class graduated in 1897. Coeducational since organization. The faculty consists of 71 professors and 313 instructors, assistants and others, a total of 384. The requirements for admission demand that the applicant possess a collegiate degree and have a knowledge of French and German (two years each of college instruction), physics and biology, such as may be obtained from a years' course, and a two years' course in chemistry. The course extends over four years of eight and one-half months each. The total fees for each year are, respectively, $611, $610, $610 and $610. Total registration for 1931-1932 was 282; graduates, 67. The fortieth session begins Oct. 4, 1932, and ends June 13, 1933. The Dean is Alan M. Chesney, M.D.

University of Maryland School of Medicine and College of Physicians and Surgeons, Lombard and Greene streets.—Organized in 1807 as the College of Medicine of Maryland. The first class graduated in 1810 In 1812 it became the University of Maryland School of Medicine. Baltimore Medical College was merged into it in 1913. In 1915 the College of Physicians and Surgeons of Baltimore was merged and the present name assumed. Coeducational since 1918. The faculty consists of 92 professors and 141 instructors and assistants, a total of 233. Two years of college work is required for admission. The course covers four years of eight months each. The fees for the four years, respectively, are $385, $375, $375 and $390 for residents of the state; for nonresidents the fees are $150 additional each year. Total registration for 1931-1932 was 420; graduates, 101. The one hundred and twenty-fifth session begins Sept. 26, 1932, and ends June 3, 1933. The Dean is J. M. H. Rowland, M.D.

MASSACHUSETTS

Boston

Boston University School of Medicine, 80 East Concord Street.—Organized in 1873 as a homeopathic institution. In 1874 the New England Female Medical College, founded in 1848, was merged into it. The first class was graduated in 1874. Became nonsectarian in 1918. Coeducational since organization. Three years of collegiate work is required for admission. The faculty includes 19 professors, 153 associates and others, a total of 172. The course covers four years: first three years, thirty-two weeks; fourth year, thirty-six weeks. Total fees for each of the four years, respectively, are $421.50, $421.50, $396.50 and $406.50. Total registration for 1931-1932 was 234; graduates, 52. The sixtieth session begins Sept. 22, 1932, and ends June 12, 1933. The Dean is Alexander S. Begg, M.D.

Harvard University Medical School, 240 Longwood Avenue.—Organized in 1782. The first class graduated in 1788. It has a faculty of 114 professors and 345 instructors and assistants, a total of 459. Candidates for admission must present a college degree or two years of work leading to such a degree with standing in the upper third of the class. The college work must include a year of physics, biology and general chemistry, a half year of organic chemistry, and a reading knowledge of French or German. The total fee for each of the four years is $400 plus $5 the first year for matriculation. The total registration for 1931-1932 was 517; graduates, 136. The one hundred and fiftieth session begins Sept. 26, 1932, and ends June 22, 1933. The Dean is David L. Edsall, M.D.

Tufts College Medical School, 416 Huntington Avenue.—Organized in 1893 as the Medical Department of Tufts College. The first class graduated in 1894. Coeducational since 1894. It has a faculty of 66 professors and 219 assistants, lecturers and others, a total of 285. A minimum of two years of collegiate work is required for admission, but applicants with degrees are given preference. The course covers four years of eight months each. The total fees for each of the four years are $400, $400, $400 and $350. Total registration for 1931-1932 was 465; graduates, 117. The thirty-seventh session begins Sept. 28, 1932, and ends June 19, 1933. The Dean is A. Warren Stearns, M.D.

MICHIGAN

Ann Arbor

University of Michigan Medical School.—Organized in 1850 as the University of Michigan Department of Medicine and Surgery. The first class graduated in 1851. Present title assumed in 1915. Coeducational since organization. It has a faculty of 22 professors, 12 associate professors, 30 assistant professors, 70 instructors and lecturers; a total of 134. The curriculum covers four years of nine months each. The total fees for Michigan students are $200, $205, $205 and $202.50 for each of the four years, respectively, plus a matriculation fee of $10; for nonresidents, $100 a year additional. The matriculation fee for nonresidents is $25. The total registration for 1931-1932 was 514; graduates, 130. The eighty-third session begins Sept. 26, 1932, and ends June 19, 1933. The Secretary is Arthur C. Curtis, M.D.

Detroit

Detroit College of Medicine and Surgery, 1516 St. Antoine Street.—Organized as the Detroit College of Medicine in 1885 by consolidation of Detroit Medical College, organized in 1868, and the Michigan College of Medicine, organized in 1880. Reorganized with present title in 1913. The first class graduated in 1886. In 1918 it became a municipal institution under the control of the Detroit Board of Education. Coeducational since 1917. Entrance requirement is an academic degree or 90 semester hours of academic credit with "combined degree" guaranteed by school of arts and sciences. The faculty consists of 33 professors, 101 lecturers and others, a total of 134. The course covers four years of nine months each and a fifth hospital intern year. The total fees for each of the first four years are, for Detroit residents, $275; for nonresidents who reside in Michigan, $375, and for nonresidents from outside the state, $400. For the fifth or intern year the resident student fee is $75, the nonresident fee is $110. The total registration for 1931-1932 was 315; graduates, 66. The forty-eighth session begins Sept. 29, 1932, and ends June 20, 1933. The Dean is W. H. MacCraken, M.D.

MINNESOTA

Minneapolis

University of Minnesota Medical School.—Organized in 1883 as the University of Minnesota College of Medicine and Surgery, reorganized in 1888 by absorption of St. Paul Medical College and Minnesota Hospital College. The first class graduated in 1889. In 1908 the Minneapolis College of Physicians and Surgeons, organized in 1883, was merged. In 1909 the Homeopathic College of Medicine and Surgery was merged. Present title in 1913. Coeducational since organization. The faculty includes 176 professors and 155 instructors and assistants, a total of 331. The curriculum covers four years of nine months each, and a year's internship in an approved hospital. The school is operated on the four-quarter plan. The entrance requirements are two years of university work, which must include six semester credits of rhetoric, eight semester credits of physics; thirteen credits of general chemistry, qualitative and quantitative analysis and organic chemistry, eight credits of zoology, and a reading knowledge of scientific German. Students are required to secure a degree of B.S. or A.B. before receiving the degree of Bachelor of Medicine (M.B.) which is granted at the end of the four-year course. The M.D. degree is conferred after a year of intern work, of advanced laboratory work, or of public health work has been completed. Classes are graduated three times a year, in March, June and December (after 1932, no December class). Total fees are $243 for residents and $318 for nonresidents, each year of three quarters; incidental fee of $6 per quarter also. The total registration for 1931-1932 was 465; graduates, 129. The forty-fourth session begins Oct. 3, 1932, and ends June 17, 1933. The Dean is Elias P. Lyon, M.D.; Dean of Medical Sciences, Richard E. Scammon, Ph.D.

MISSISSIPPI

University

University of Mississippi School of Medicine.—Organized in 1903. Coeducational since organization. Gives only the first two years of the medical course. A clinical department was established at Vicksburg in 1908 but was discontinued in 1910 after graduating one class. The session extends over eight and one-half months. Entrance requirement is two years of collegiate work. The faculty numbers 8 professors and 7 instructors, assistants and others, a total of 15. The total fees each year for residents are $200.75; for nonresidents, $50 additional per year The total registration for 1931 1932 was 53 The thirtieth session begins Sept 21, 1932, and ends June 4, 1933 The Dean is P L Mull, M D

MISSOURI

Columbia

UNIVERSITY OF MISSOURI SCHOOL OF MEDICINE—Organized at St Louis in 1845, was discontinued in 1855 but was reorganized at Columbia in 1872 Teaching of the clinical years was suspended in 1909 and restored in 1931 Effective September, 1932, the third year and the proposed fourth year will be discontinued Coeducational since 1872 The faculty includes 13 professors and 10 assistant professors, lecturers and others, a total of 23 The entrance requirements are 90 semester hours of college work, including French or German, 8 hours, general zoology, 8 hours, physics, 8 hours, inorganic chemistry, 8 hours, organic chemistry, 5 hours, and general bacteriology, 3 hours Total fees for the first year are $170, for the second, $150 Nonresidents of the state pay $25 per term extra Total registration for 1931 1932 was 93 The next session begins Sept 12, 1932, and ends June 7, 1933 The Dean is Edgar Allen, Ph D

St Louis

ST LOUIS UNIVERSITY SCHOOL OF MEDICINE 1402 South Grand Boulevard—Organized in 1901 as the Marion Sims Beaumont Medical College by union of Marion Sims Medical College, organized in 1890, and Beaumont Hospital Medical College, organized in 1886 First class graduated in 1902 It became the Medical School of St Louis University in 1903 The faculty is composed of 77 professors and 227 instructors and assistants, a total of 304 The requirement for admission is a qualitative standard of two years of collegiate study in the customary subjects, but applicants presenting meritorious credit in excess of the two year minimum are accepted by preference The curriculum covers four years of thirty two weeks each The summer is optional and offers courses academically equivalent to those in the regular session The total fees for the four years, respectively, are $395, $390, $390 and $410 The total registration for 1931 1932 was 514, graduates, 104 The next session begins Sept 21, 1932, and ends June 1, 1933 The Dean is Alphonse M Schwitalla, S J, Ph D

WASHINGTON UNIVERSITY SCHOOL OF MEDICINE, Kingshighway and Euclid Avenue—Organized in 1842 as the Medical Department of St Louis University The first class graduated in 1843 In 1855 it was chartered as an independent institution under the name of St Louis Medical College In 1891 it became the Medical Department of Washington University In 1899 it absorbed the Missouri Medical College Coeducational since 1918 The faculty comprises 52 professors and 243 lecturers, instructors and others, a total of 295 Four years of college work is required for admission, including courses in English, physics, chemistry and biology, and a reading knowledge of German or French The course is four years of eight months each The total fees for the four years are, respectively, $424, $419, $419 and $424 The total registration for 1931 1932 was 333, graduates, 88 The next session begins Sept 22, 1932, and ends June 6, 1933 The Dean is W McKim Marriott, M D

NEBRASKA

Omaha

CREIGHTON UNIVERSITY SCHOOL OF MEDICINE, 306 North Fourteenth Street—Organized in 1892 as the John A Creighton Medical College The first class graduated in 1893 Present title in 1921 Coeducational since organization It has a faculty of 61 professors and 61 instructors, lecturers and assistants, a total of 122 Two years of collegiate work is required for admission The curriculum covers four years of eight months each The total fees each year for the four years are respectively, $393 50, $391, $348 50 and $346 Total registration for 1931 1932 was 288, graduates, 51 The fifty first session begins Sept 22, 1932, and ends June 1, 1933 The acting dean is John J McInerny, S J

UNIVERSITY OF NEBRASKA COLLEGE OF MEDICINE, Forty Second Street and Dewey Avenue—Organized in 1881 as the Omaha Medical College The first class graduated in 1882 It became the Medical Department of Omaha University in 1891 In 1902 it affiliated with the University of Nebraska with the present title The instruction of the first two years was given at Lincoln and of the last two at Omaha until 1913, when the work of all four years was transferred to Omaha Coeducational since 1882 The faculty is composed of 70 professors and 58 lecturers and instructors, a total of 128 Sixty five semester hours of collegiate work is required for admission, including courses in physics chemistry and zoology The fees for each of the four years respectively, are $217, $212, $212 and $212 Total registration for 1931 1932 was 336, graduates, 78 The next session begins Sept 16, 1932, and ends June 5, 1933 The Dean is C W M Poynter, M D

NEW HAMPSHIRE

Hanover

DARTMOUTH MEDICAL SCHOOL—Organized as New Hampshire Medical Institute in 1797 The first class graduated in 1798 It is under the control of the trustees of Dartmouth College Clinical teaching was discontinued in 1914 The faculty consists of 16 professors and 11 instructors, a total of 27 Three years of collegiate work is required for admission The course covers nine calendar months in each year, or eight months of actual teaching Candidates for the A B degree in Dartmouth College may substitute the work of the first year in medicine for that of the senior year in the academic department The fees for the first year are $410 and $400 for the second year The total registration for 1931 1932 was 40 The next session begins Sept 22, 1932, and ends June 20, 1933 The Dean is John P Bowler, M D

NEW YORK

Albany

ALBANY MEDICAL COLLEGE, 47 New Scotland Avenue—Organized in 1838 The first class graduated in 1839 It became the Medical Department of Union University in 1873 In 1915, Union University assumed educational control Coeducational since 1915 The faculty is composed of 24 professors and 114 instructors, assistants and others, a total of 138 Two years of collegiate work, including college courses in physics, chemistry (including organic and analytic), biology English and a modern foreign language is required for admission The curriculum covers four years of eight months each The total fees for the four years, respectively, are $430, $405 $305 and $305 The total registration for 1931-1932 was 120 graduates 27 The one hundred and second session begins Sept 26, 1932, and ends June 12, 1933 The Dean is Thomas Ordway, M D

Brooklyn

LONG ISLAND COLLEGE OF MEDICINE 350 Henry Street—Organized in 1858 as the Long Island College Hospital The first class graduated in 1860 and the last class in 1930 Reorganized with a new charter in 1930 as the present institution The first class graduated in 1931 Coeducational It has a faculty of 113 professors and 111 assistants, instructors and others, a total of 224 Seventy two semester hours of collegiate work including college courses in physics chemistry and biology are required for admission The course covers four years of eight months each The total fees for each of the four years are, respectively, $545 $560 $530 and $560 Total registration for 1931 1932 was 433, graduates, 110 The second session begins Oct 3 1932, and ends June 10 1933 The Dean is Adam M Miller A M

Buffalo

UNIVERSITY OF BUFFALO SCHOOL OF MEDICINE 24 High Street—Organized in 1846 The first class graduated in 1847 It absorbed the Medical Department of Niagara University in 1898 Coeducational since organization The faculty is composed of 71 professors and 154 associates, assistants and others, a total of 225 Two years of collegiate work, including college courses in physics, chemistry, biology, English and French or German, is required for admission The course covers four years of eight months each The total fees for each of the four years are, respectively $527 $522, $517 and $527 Total registration for 1931 1932 was 273, graduates 59 The eighty seventh session begins Oct 3, 1932 and ends June 14, 1933 The Dean is Edward W Koch, M D

New York

COLUMBIA UNIVERSITY COLLEGE OF PHYSICIANS AND SURGEONS 630 West One Hundred and Sixty Eighth Street—The medical faculty of Columbia College, then known as King s College, was organized in 1767 Instruction was interrupted by the War of the Revolution The faculty was reestablished in 1792 and merged in 1814 with the College of Physicians and Surgeons, which had received an independent charter in 1807 In 1860 the College of Physicians and Surgeons became the Medical Department of Columbia College This merger became permanent by legislative enactment in 1891 Columbia College became Columbia University in 1896 The Medical School has been coeducational since 1917 The faculty is composed of 191 professors and 366 instructors, demonstrators and others a total of 557 Three years of collegiate work including courses in physics chemistry biology and English constitutes the minimum requirement for admission The work covers four years of eight months each The total fees for the four years, respectively, are $535, $520, $520 and $540 Total registration for 1931 1932 was 408, graduates 102 The one hundred and twenty fifth session begins Sept 28, 1932, and ends June 7, 1933 The Dean is Willard C Rappleye, M D

CORNELL UNIVERSITY MEDICAL COLLEGE York Avenue and Sixty-Ninth Street—Organized in 1898 The work of the first year may be taken either in Ithaca or in New York Coeducational since organization The faculty is composed of 112 professors and 175 assistants, lecturers, instructors and others, a total of 287 All candidates for admission must be graduates of approved colleges or scientific schools or seniors of approved colleges that will permit them to substitute the first year of this medical school for the fourth year of their college course and will confer on them the bachelor degree on the completion of the first year's work The candidate must also have a knowledge of physics, chemistry, biology, English and a modern language The fees for each of the four years are respectively, $510, $500, $510 and $525 Total registration for 1931 1932 was 439 (including Ithaca students), graduates 60 The thirty fifth session begins Sept 26 1932, and ends June 8, 1933 The Director is G Canby Robinson, M D

NEW YORK HOMEOPATHIC COLLEGE AND FLOWER HOSPITAL 450 East Sixty Fourth Street—Organized in 1858 Incorporated in 1860 as the Homeopathic Medical College of the State of New York The title New York Homeopathic Medical College was assumed in 1869, present title in 1908 The first class graduated in 1861 Coeducational since 1919 Two years of collegiate work is required for admission The course covers four years of eight months each It has a faculty of 53 professors and associate professors, 18 assistant professors and 98 lecturers and assistants, a total of 169 The total fees for the four years are, respectively, $540, $530, $530 and $560 Total registration for 1931 1932 was 332, graduates, 78 The seventy third session begins Sept 19 1932, and ends June 6, 1933 The Dean is Claude A Burrett, M D

For matriculation, at least two years in a college of arts and science or an equivalent training is required, including one year of Latin, a reading knowledge of French or German, and at least a year's work in physics, chemistry and biology. It has a faculty of 64 professors and 67 lecturers, instructors and others, a total of 131. The fees for each year are, respectively, $150, $82, $60 and $43. An additional fee of $200 is charged for nonresidents. The total registration for 1931-1932 was 318; graduates, 52. The twenty-fifth session begins Sept. 21, 1932, and ends June 19, 1933. The Dean is C. R. Bardeen, M.D.

Milwaukee

Marquette University School of Medicine, 561 North Fifteenth Street.—Organized in December, 1912, by the merger of the Milwaukee Medical College and the Wisconsin College of Physicians and Surgeons. Coeducational since organization. It has a faculty of 165. The entrance requirements are sixty-four semester hours of college work, including courses in physics, chemistry, biology, and a modern foreign language. The curriculum covers four years of eight and a half months each, and one year's internship in an approved hospital. The fees for the four years, respectively, are $389, $379, $379 and $364. The total registration for 1931-1932 was 259; graduates, 61. The twenty-first session begins Sept. 26, 1932, and ends June 7, 1933. The Dean is B. F. McGrath, M.D.

CANADA

Alberta

University of Alberta Faculty of Medicine, Edmonton.—Organized in 1913. Coeducational since organization. Has given the complete six-year medical course since 1924. The faculty includes 41 professors and 45 instructors, assistants and others, a total of 86. Fees for first year are $175 and $225 for other five years. The registration for 1931-1932 was 135; graduates, 22. The twentieth session begins Sept. 26, 1932, and ends May 16, 1933. The Dean is Allan Coats Rankin, M.D.

Manitoba

University of Manitoba Faculty of Medicine, Corner of Emily and Bannatyne Avenue, Winnipeg.—Organized in 1883 as Manitoba Medical College; first class graduated in 1886, and a class graduated each subsequent year. The college transferred all its property to the University of Manitoba in 1919 and assumed the present title. Coeducational since organization. The faculty includes 46 professors, 79 instructors and assistants, a total of 125. The total fees for the five years, respectively, are $261, $251, $261, $261 and $120. Matriculation requirements include two years of college work in the faculty of arts and science of a recognized university subsequent to the complete high school course required for entrance to the latter. The course extends over four years of eight months each and a hospital internship. Total registration for 1931-1932 was 241; graduates, 34. The next session begins Sept. 22, 1932, and ends May 27, 1933. The Dean is A. T. Mathers, M.D.

Nova Scotia

Dalhousie University Faculty of Medicine, Halifax.—Organized in 1867. Incorporated as the Halifax Medical College in 1875. Reorganized as an examining faculty, separate from the Halifax Medical College, in 1885. In 1911, in accordance with an agreement between the Governors of Dalhousie University and the Corporation of the Halifax Medical College, the work of the latter institution was discontinued and a full teaching faculty was established by the university. By an arrangement between Dalhousie University and the Provincial Medical Board of Nova Scotia, the final professional examinations are conducted conjointly by the university and the board, and candidates may qualify at the same time for their academic degrees and the provincial license. First class graduated in 1872. Coeducational since 1871. It has a faculty of 27 professors and 42 demonstrators, lecturers and others, a total of 69. Requires for matriculation two years of arts and a graded course of four years and a hospital internship of one year. The fees are $277, $277, $282 and $262 for each year, respectively. The total registration in regular classes for 1931-1932 was 142; graduates, 34. The next session begins Sept. 13, 1932, and ends May 16, 1933. The Dean is H. G. Grant, M.D.

Ontario

Queen's University Faculty of Medicine, Kingston.—Organized 1854, first class graduated in 1855, and a class graduated each subsequent year. The faculty was originally a department of the university, but a separation took place in 1866, when the school was conducted under the charter of the Royal College of Physicians and Surgeons at Kingston. It admitted women from 1880 until 1883. In 1892 the school again became a part of Queen's University. The faculty numbers 55. The fees for the six years are, respectively, $175.75, $185.75, $185.75, $210.75, $210.75 and $240.75. The last includes the fee of $30 for the M.D., C.M. degrees. The course covers six years of thirty teaching weeks each, the first including courses in physics, chemistry, biology, history or economics or English. The total registration in 1931-1932 was 239; graduates, 48. The next session begins Sept. 29, 1932, and ends May 24, 1933. The Dean is Frederick Etherington, M.D.

University of Western Ontario Medical School, Ottaway Avenue, London.—Organized in 1881 as the Western University Faculty of Medicine; first class graduated in 1883, and a class graduated each subsequent year. Present title in 1923. The medical school has been under the control of the Board of Governors of the University of Western Ontario since 1913. Coeducational since 1913. The faculty numbers 71. Two years of premedical college work, including courses in physics, chemistry and biology, is required for admission to a four year medical course—all of which is referred to as a six year medical course The total fees to residents of Canada for the last four years, respectively, are $200, $200, $208 and $233. The registration for 1931-1932 was 140, graduates, 37. The next session begins Sept 21, 1932, and ends June 2, 1933 The Dean is A. B. Macallum, M D

University of Toronto Faculty of Medicine, Toronto—Organized in 1843 as the Medical Faculty of King's College Abolished in 1853 Reestablished in 1887. In 1902 it absorbed Victoria University, Medical Department, and in 1903 it absorbed the Medical Faculty of Trinity University Coeducational since 1903 The course of study covers six years of eight months each, the first two being devoted largely to physics, chemistry, biology and cultural courses in history, science and English It has a faculty of 62 professors and 238 lecturers, associates and others, a total of 300 The fees are $170 for the first year, for the second, $220, $280 for the third year, $220 for the fourth and fifth years, and $243 for the sixth year The total registration for 1931 1932 was 663; graduates, 135 The next session begins Sept 27, 1932, and ends May 20, 1933. The Dean is J G FitzGerald, M D

Quebec

McGill University Faculty of Medicine, 3640 University Street, Montreal—Founded 1824 as Montreal Medical Institution, became the Medical Faculty of McGill University in 1829, first class graduated under the university auspices in 1833. No session between 1836 1839, owing to political troubles In 1905 it absorbed the Faculty of Medicine of the University of Bishop College Coeducational since 1919 The course consists of three premedical years, and five medical years of eight months each The faculty consists of 66 professors and 126 lecturers and others, a total of 192. The total fees for each of the five medical years are $267. The total registration for 1931-1932 was 467, graduates, 99 The next session begins Sept 14, 1932, and ends April 25, 1933 The Dean is Charles F. Martin, M D.

University of Montreal Faculty of Medicine, 1265 St. Denis Street, Montreal—Organized in 1843, incorporated in 1845 as the Montreal School of Medicine and Surgery. In 1891, by act of Parliament, the Medical Faculty of Laval University (organized in 1878) was absorbed Present name by act of Parliament in 1920 A class was graduated in 1843 and in each subsequent year. Coeducational since 1925 The faculty numbers 103 The course covers one premedical and five medical years, including a hospital internship. The total fees for each of the five years, respectively, are $240, $220, $262, $232 and $218. The total registration for 1931 1932 was 232, graduates, 35 The next session begins Sept 15, 1932, and ends June 15, 1933 The Dean is Louis de Lotbiniere Harwood, M D

Laval University Faculty of Medicine, Quebec—The Quebec School of Medicine, organized in 1848, became in 1852 the Laval University Faculty of Medicine, first class graduated in 1855, and a class graduated each subsequent year The faculty numbers 88 The fees for each of the medical years are $160, $170, $160, $160 and $180 for residents of Canada Nonresidents are charged an extra fee of $190 each year The course covers one premedical year, including preliminary courses in physics, chemistry and biology, and five medical years Total registration for 1931-1932 was 255, graduates, 51. The next session begins Sept 13, 1932, and ends May 31, 1933 The Dean is Arthur Rousseau, M D

Saskatchewan

University of Saskatchewan School of Medical Sciences, Saskatoon—Organized in 1926. Coeducational Offers the first two years only following a minimum of two years' university work, mainly in physics, chemistry and biology Students require three more years for graduation, making in all seven years from matriculation. The medical faculty includes 8 professors and 4 lecturers and assistants, a total of 12. The fees are $120 for each year The total registration for 1931-1932 was 52 The next session begins Sept. 23, 1932, and ends May 12, 1933. The Dean is W S Lindsay, M D.

COLLEGE NEWS

The following current topics regarding medical schools have been reported:

University of California Medical School.—Plans are being prepared for the construction of a new building which will house the activities of the outpatient department of the University of California Hospital. The Christine Breon Fund became available for medical research in the medical school and the Lillie Spreckles Wegeforth Fund for research on respiratory infections.

Yale University School of Medicine Buildings Completed.—The Sarah Way Tompkins Memorial Pavilion of the New Haven Hospital, providing modern ward facilities for surgical cases, opened early in June, 1932

George Washington University School of Medicine.—During the past year a new four story laboratory building, adjoining the medical school, has been constructed This building will house the department of bacteriology, hygiene and preventive medicine, animal quarters for experimental work for the entire school, a central diagnostic laboratory for the hospital, a hospital record room, and a teaching laboratory for clinical microscopy. The old medical building is being completely remodeled and all laboratories are being newly equipped for teaching and investigative work Twelve new full-time men have been added to the teaching staff and the university has increased its appropriation to the medical school in order to promote a program of teaching and research along the most modern lines. In addition, many improvements have been made in the physical plant of the university hospital, adjoining the school of medicine, and plans have been drawn for a new addition to the dispensary and the installation of a new department of radiology.

Indiana University School of Medicine.—The Rotary Convalescent Home has been completed and placed in operation. Anonymous donors gave the well baby clinic, $5,500; oxygen chambers, $7,000; students' loan fund, $4,000; general use, $3,000 The Eli Lilly Fund has also contributed $5,000 for five years for research

University of Minnesota Medical School.—A new medical science building has been erected to be used primarily for dentistry but also for some medical classes

St. Louis University School of Medicine.—During the session 1931-1932, notable progress has been made toward the completion of a new unit of the University Hospital, the Firmin Desloge Hospital. Increased teaching facilities have been secured by the opening of a pediatric division at St Mary's Hospital, the division containing thirty-eight beds, with facilities in the other sections of the hospital for ten or more additional patients. The staff reorganization and the new program for medical administration at Mount St. Rose Sanitarium has been completed and has been functioning successfully during the second semester. The program for developing graduate fellowships has been enlarged, so that during 1931-1932 nine new appointments and six reappointments have been made.

University of Nebraska College of Medicine.—A reserve fund of $1,500 for special research was received and an endowment for the department of pediatrics from the estate of Dr. H. M McClanahan, former chairman of the department, the present valuation of which is $30,000. A sixty student addition to the present nurses' home is ready for occupancy.

Albany Medical College.—Four fellowships have been established, three through the Littauer Foundation and the other through the Schepp Foundation An appropriation was received from the Rockefeller Foundation for activities of the Regional Extension Department and from the General Electric Company for special research and other purposes

Columbia University College of Physicians and Surgeons.—The Institute of Ophthalmology of the Presbyterian Hospital is now in process of construction, with a capacity of 110 beds

New York Homeopathic Medical College and Flower Hospital.—Gifts amounting to $132,625 have been received from Mr. Eversley Childs, Sr, a trustee, Mrs. Eversley Childs, Sr, Charles Strauss, a trustee, the Flower Hospital Ladies Auxiliary, and the estates of various individuals.

University and Bellevue Hospital Medical College.—Gifts amounting to $205,779.47, principally for research, have been received.

Duke University School of Medicine.—The Nurses' Home was completed in June, 1932.

University of Cincinnati College of Medicine.—A gift of $3,000 was received from Mrs. Christian R. Holmes to prepare and equip the top floor of the Christian R. Holmes Hospital for Ophthalmological Service.

University of Oregon Medical School.—An appropriation for research from the Rockefeller Foundation of $13,000 was received, to cover a two year period.

Jefferson Medical College of Philadelphia.—The Curtis Clinic Building, containing all the outpatient departments, was opened.

Meharry Medical College.—The new plant, including medical school, hospital and nurses' home, was completed in course is four years of eight months each The fees for each of the four years, respectively, are $312, $297, $282 and $287 Total registration for 1931-1932 was 356, graduates, 67 The thirty third session begins Sept 26, 1932, and ends May 29, 1933 The Dean is W H Moursund, M D

Galveston

University of Texas School of Medicine, 912 Avenue B — Organized in 1891 The first class graduated in 1892 Coeducational since organization It has a faculty of 42 professors and 24 lecturers and instructors, a total of 66 The curriculum covers four years of eight months each The entrance requirement is two years of collegiate work in addition to a four year high school education The freshman class is limited to 100 students on a scholarship basis, only Texans are accepted The total fees for the four years, respectively, are $82, $78, $66 and $80 Total registration for 1931 1932 was 328, graduates, 71 The forty second session begins Oct 1, 1932, and ends May 31, 1933 The Dean is George E Bethel, M D

UTAH

Salt Lake City

University of Utah School of Medicine — Organized in 1906 Coeducational since organization Gives only first two years of medical course Each school year covers thirty six weeks Three years of collegiate work is required for admission The medical faculty consists of 7 professors and 17 lecturers and assistants, a total of 24 The fees are $190 for the first year and $200 for the second year Total registration for 1931-1932 was 68 The twenty sixth session begins Sept 27, 1932, and ends June 3, 1933 The Dean is L L Daines, M D

VERMONT

Burlington

University of Vermont College of Medicine, Pearl Street, College Park — Organized with complete course in 1822 Classes graduated in 1823 to 1836, inclusive, when the school was suspended It was reorganized in 1853 and classes were graduated in 1854 and in all subsequent years Coeducational since 1920 It has a faculty of 30 professors and 39 lecturers, instructors, preceptors and others, a total of 69 Seventy two hours of college work in addition to a four year high school education is required for admission The course of study covers four years of nine months each For residents of Vermont the tuition fee is $300 each session Nonresidents are charged an additional $75 each session A student activity fee of $30 is charged all students not holding academic degrees or in attendance four years previously, and a $25 fee for the Doctor's degree The total registration for 1931 1932 was 156, graduates, 36 The next session begins Sept 16, 1932, and ends June 19, 1933 The Dean is J N Jenne, M D

VIRGINIA

Charlottesville

University of Virginia Department of Medicine — Organized in 1827 Classes were graduated in 1828 and in all subsequent years except 1865 Coeducational since the session 1920 1921 It has a faculty of 31 professors and 38 lecturers, instructors, assistants and others a total of 69 The requirements for admission are the completion of a four year high school course, or its equivalent, and two years of college work devoted to English, mathematics, chemistry, physics and biology For residents of Virginia the total fees for the four years, respectively, are $377 50, $355, $330 and $325 Nonresidents are charged an additional $50 each year The total registration for 1931 1932 was 241, graduates, 49 The one hundred and ninth session begins Sept 15, 1932, and ends June 13, 1933 The Dean is J Carroll Flippin, M D

Richmond

Medical College of Virginia, Twelfth and Clay streets — Organized in 1838 as the Medical Department of Hampden Sydney College Present title was taken in 1854 In 1913 the University College of Medicine was merged In 1914 the North Carolina Medical College was merged Coeducational since 1918 Classes were graduated in 1839 and in all subsequent years It has a faculty of 60 professors and 80 lecturers, instructors and others, a total of 140 The requirements for admission are a four year high school education and in addition two years of collegiate work, including courses in physics, chemistry, biology and English The course covers four years of eight and one half months each Total fees for the four years, respectively, are $307, $307, $292 and $322 Nonresidents are charged an additional $100 each year The total registration for 1931-1932 was 362, graduates, 91 The ninety fifth session begins Sept 13, 1932, and ends May 30, 1933 The Dean is Lee E Sutton, Jr, M D

WEST VIRGINIA

Morgantown

West Virginia University School of Medicine — Organized in 1902 and gives only the first two years of the medical course Coeducational since organization Sixty four semester hours of college work is required for admission, and the bachelor's degree will be granted to those who finish the two years in medicine Session extends through nine months The faculty numbers 11 professors and 11 lecturers, instructors, assistants and others, a total of 22 Fees for residents of the state, $115 each year, for nonresidents, $365 The total registration for 1931-1932 was 142 The next session begins Sept 8, 1932, and ends June 6, 1933 The Dean is John N Simpson, M D

WISCONSIN

Madison

University of Wisconsin Medical School, 412 North Charter Street — Organized in 1907. Gave only first two years of the medical course until 1925, when the clinical years were added Coeducational since organization For matriculation, at least two years in a college of arts and science or an equivalent training is required, including one year of Latin, a reading knowledge of French or German, and at least a year's work in physics, chemistry and biology It has a faculty of 64 professors and 67 lecturers, instructors and others, a total of 131 The fees for each year are, respectively, $150, $82, $60 and $43 An additional fee of $200 is charged for nonresidents The total registration for 1931 1932 was 318, graduates, 52 The twenty fifth session begins Sept 21, 1932, and ends June 19, 1933 The Dean is C R Bardeen, M D

Milwaukee

Marquette University School of Medicine, 561 North Fifteenth Street — Organized in December, 1912, by the merger of the Milwaukee Medical College and the Wisconsin College of Physicians and Surgeons Coeducational since organization It has a faculty of 165 The entrance requirements are sixty four semester hours of college work, including courses in physics, chemistry, biology, and a modern foreign language The curriculum covers four years of eight and a half months each, and one year's internship in an approved hospital The fees for the four years, respectively, are $389, $379, $379 and $364 The total registration for 1931-1932 was 259, graduates, 61 The twenty first session begins Sept 26, 1932, and ends June 7, 1933 The Dean is B F McGrath, M D

CANADA

Alberta

University of Alberta Faculty of Medicine, Edmonton — Organized in 1913 Coeducational since organization Has given the complete six year medical course since 1924 The faculty includes 41 professors and 45 instructors, assistants and others, a total of 86 Fees for first year are $175 and $225 for other five years The registration for 1931 1932 was 135, graduates, 22 The twentieth session begins Sept 26, 1932, and ends May 16, 1933 The Dean is Allan Coats Rankin, M D

Manitoba

University of Manitoba Faculty of Medicine, Corner of Emily and Bannatyne Avenue, Winnipeg — Organized in 1883 as Manitoba Medical College, first class graduated in 1886, and a class graduated each subsequent year The college transferred all its property to the University of Manitoba in 1919 and assumed the present title Coeducational since organization The faculty includes 46 professors, 79 instructors and assistants, a total of 125 The total fees for the five years respectively, are $261, $251, $261, $261 and $120 Matriculation requirements include two years of college work in the faculty of arts and science of a recognized university subsequent to the complete high school course required for entrance to the latter The course extends over four years of eight months each and a hospital internship Total registration for 1931 1932 was 241, graduates, 34 The next session begins Sept 22, 1932, and ends May 27, 1933 The Dean is A T Mathers, M D

Nova Scotia

Dalhousie University Faculty of Medicine, Halifax — Organized in 1867 Incorporated as the Halifax Medical College in 1875 Reorganized as an examining faculty, separate from the Halifax Medical College, in 1885 In 1911, in accordance with an agreement between the Governors of Dalhousie University and the Corporation of the Halifax Medical College, the work of the latter institution was discontinued and a full teaching faculty was established by the university By an arrangement between Dalhousie University and the Provincial Medical Board of Nova Scotia, the final professional examinations are conducted conjointly by the university and the board, and candidates may qualify at the same time for their academic degrees and the provincial license First class graduated in 1872 Coeducational since 1871 It has a faculty of 27 professors and 42 demonstrators, lecturers and others, a total of 69 Requires for matriculation two years of arts and a graded course of four years and a hospital internship of one year The fees are $277, $277, $282 and $262 for each year, respectively The total registration in regular classes for 1931-1932 was 142, graduates, 34 The next session begins Sept 13, 1932, and ends May 16, 1933 The Dean is H G Grant, M D

Ontario

Queen's University Faculty of Medicine, Kingston — Organized 1854, first class graduated in 1855, and a class graduated each subsequent year The faculty was originally a department of the university, but a separation took place in 1866, when the school was conducted under the charter of the Royal College of Physicians and Surgeons at Kingston It admitted women from 1880 until 1883 In 1892 the school again became a part of Queen's University The faculty numbers 55 The fees for the six years are, respectively, $175 75, $185 75, $185 75, $210 75, $210 75 and $240 75 The last includes the fee of $30 for the M D, C M degrees The course covers six years of thirty teaching weeks each, the first including courses in physics, chemistry, biology, history or economics or English The total registration in 1931-1932 was 239, graduates, 48 The next session begins Sept 29, 1932, and ends May 24, 1933 The Dean is Frederick Etherington, M D

University of Western Ontario Medical School, Ottawa Avenue, London — Organized in 1881 as the Western University Faculty of Medicine, first class graduated in 1883, and a class graduated each subsequent year Present title in 1923 The medical school has been under the control of the Board of Governors of the University of Western Ontario since 1913 Coeducational since 1913 The faculty numbers 71 Two years of premedical college work, including courses in physics,

SATURDAY, AUGUST 27, 1932

MEDICAL EDUCATION, 1932

The survey of medical education presented elsewhere in this issue clearly formulates one of the most serious problems now confronting our profession. Chart 1 shows that the number of medical graduates during the last ten years has steadily increased and that it now exceeds, by 50 per cent, the average annual loss to the profession through death. Moreover, there is a growing tendency for prospective medical students in excess of the numbers which our own schools can accommodate to seek their professional training in Europe or Canada. The number of these expatriated students, so far as reported to us, is this year 63 per cent larger than in 1930-1931. It may reasonably be expected that after graduation these men and women will return to this country to practice, adding several hundred more to the number annually licensed. The United States already has more physicians in proportion to its population than any other country in the world; if this ratio is still further increased, it is evident that an oversupply of doctors threatens, with an inevitable lowering of the standards of the profession. Perhaps there is need for professional birth control.

Seldom does any one assert that the test of fitness to practice, administered by the state licensing boards, is too severe. Yet even by this test the graduates of the majority of the European schools make a poor showing. The analysis of the state board records for five years seems to afford justification for the requirement of an additional period of training in the case of most of these physicians who have been educated abroad.

A powerful incentive to raising the standards of hospitals has been the desire for qualified interns, and hence for the approval of the Council on Medical Education and Hospitals. The result of this activity has been an increase in the number of hospitals approved for intern training, which now have places for 1,325 more men or women than the schools annually turn out. This situation constitutes a hardship for those institutions which are unable to secure adequately trained men or women as interns. However, competition is undoubtedly impelling many hospitals to improve greatly their facilities for intern training. Perhaps a solution of this problem may be found in lengthening the average duration of the internship and the more definite assignment of surgery to the rôle of a specialty.

CUBAN PHYSICIANS REVOLT

Newspapers recently announced that the physicians of Cuba employed by the mutual aid societies had revolted against the terms of their employment and that at the request of the president of Cuba they had agreed to postpone their strike for seventy-two hours. The president is studying the dispute, which is precipitated by a refusal of the societies to drop from their membership lists all persons financially able to pay regular fees for medical attendance.

The situation thus precipitated in Cuba was called to the attention of the House of Delegates of the American Medical Association in 1927 by Dr. J. M. Penichet, professor of ophthalmology in the University of Havana. The conditions of medical practice in Cuba are unusual. The population is slightly over 3,000,000 and there are about 3,000 physicians practicing in the island. This would seem to indicate approximately 1,000 available patients for each physician, whereas actually such is not the case. Some two thirds of the population are affiliated with the Spanish mutual aid societies. About fifty years ago the Spaniards established this form of practice primarily to take care of laborers. For the sum of $2 a month, members of the society are entitled to medical care in case of illness. In addition, the societies have developed clubhouses, schools, libraries, gymnasiums, ballrooms and similar amusements, and in some instances they own banks. Physicians are employed on small salaries to provide medical care. There are approximately twenty of these health societies. One of them has at least 60,000 members and another some 20,000 members. In addition to hospitals they have exceedingly ornate and handsome clubhouses, which constitute a rallying place for their membership. Shortly the plantation owners and other wealthy patrons of these organizations decided to avail themselves of the same privileges as were accorded to the laborers. As a result the private practice of medicine began to fall into desuetude and therewith the medical profession itself began to retrograde. In his address to the American Medical Association in 1927, Professor Penichet pointed out that the mutual aid societies were able to function largely through exploitation of the medical profession. The physicians formed a federation to oppose these powerful trusts and to free the medical profession. Previously to 1927 the profession had revolted twice, and there has been constant conflict since that time.

In a trip recently made to Cuba by Dr. George H. Kress, editor of *California and Western Medicine*, he

September, 1931, and the session of 1931-1932 opened in the new buildings, with new equipment

Vanderbilt University School of Medicine.—An appropriation of $250,000 was made by the Rockefeller Foundation for research over a period of eight years, an appropriation of $50,000 was made by the General Education Board for the purchase of books and periodicals by the medical library to be distributed over a period of four years, and a gift of $3,600 by nieces and nephews of Mr Leslie Warner of Nashville (plus a similar amount donated by Vanderbilt University), to be known as the Leslie Warner Fund for the Study and Treatment of Cancer, was received

University of Texas School of Medicine—The dedication of the John Sealy Hospital Outpatient Department, the Medical Laboratory Building and the Rebecca Sealy Residence for Nurses occurred May 30-31

Medical College of Virginia—Gifts amounting to $65,601 81 for the St Philip Hospital and its school of nursing library, the outpatient department, postgraduate clinic, crippled children's clinic, research in pharmacology and toward the maintenance of the library, were received A college library is under construction and will be ready for use during the session 1932-1933

Marquette University School of Medicine.—A new medical building, erected at a cost of $500,000, is ready for occupancy and all activities and classes of the medical school will be resumed in the new building for the session 1932-1933 Opportunities will be offered for graduate study in the basic sciences in correlation with clinical work in the various hospitals of the community The building will also afford accommodations for some of the basic scientific departments of the dental school

McGill University Faculty of Medicine.—A gift of $1,232 652 was received from the Rockefeller Foundation for the endowment of a Neurological Institute

Laval University Faculty of Medicine.—A new amphitheater, new equipment and a new museum have been provided for the department of anatomy New buildings have been erected for the Institut de Biologie and Institut du Cancer at Quebec

THE ASSOCIATION OF AMERICAN MEDICAL COLLEGES

The requirements for admission to and graduation from colleges holding membership in the Association of American Medical Colleges, as defined in its By Laws, are

1 Satisfactory completion of a minimum of collegiate instruction, as provided below in subsection I, or by

2 Examination, as provided in subsection II

SUBSECTION I—The minimum of collegiate instruction required for entrance to medical schools and medical colleges in membership in the association shall be 60 semester hours [1] of work which shall include the subjects hereinafter specified, in institutions approved by accrediting agencies acceptable to the executive council of the association Exception may be made under this section in that any member may admit applicants who have fulfilled the requirements in American or foreign institutions not approved by such accrediting agencies, provided that all admissions so made shall be reported to the executive council and shall be published in the next annual report of the council

All collegiate instruction given in satisfaction of this requirement must be based on the same entrance requirements and must be of the same quality and standard of instruction as that required for a baccalaureate degree in the institution in which the candidate receives his preparation

The sixty semester hours of collegiate instruction, indicated above, shall include a minimum total number of semester hours in each of certain required subjects and the specified science subjects shall include a minimum number of semester hours of laboratory work as follows

Requested Subjects	Minimum Total Semester Hours	Minimum Semester Hours of Laboratory Work
1 General chemistry (*a*)	8	4*
Organic chemistry (*b*)	4	0
2 Physics (*c*)	8	2*
3 Biology (*d*)	8	4*
4 English literature and composition (*e*)	6	

* *Included in minimum total semester hours*

Explanations as to content in each of these required college subjects together with suggestions to desirable additional study in certain subjects are as follows

(*a*) *General Chemistry*—Eight semester hours required, including 4 semester hours of laboratory work In the interpretation of this rule, work in qualitative analysis may be included as part of general chemistry [2]

(*b*) *Organic Chemistry*—A completed course of 4 semester hours required, consisting of didactic exercises, which should cover a discussion of the aliphatic, carbocyclic and heterocyclic series [3]

(*c*) *Physics*—Eight semester hours required, of which 2 semester hours shall consist of laboratory work It is urged that this course be preceded by a course in plane trigonometry [4]

(*d*) *Biology*—Eight semester hours required, of which at least 4 semester hours shall consist of laboratory work This requirement may be satisfied by a course of 8 semester hours in either general biology or zoology, or by courses of 4 semester hours each in zoology and botany, but not by botany alone Courses in physiology and hygiene, sanitation, entomology, bacteriology, histology and similar subjects covered in the medical curriculum shall not be accepted as part of the premedical college requirement in biology [5]

Students who present at least 90 semester hours of college work may substitute for the foregoing biologic requirements at least 8 semester hours in the psychologic or sociologic sciences

(*e*) *English Composition and Literature*—The usual introductory college course of 6 semester hours or its equivalent is required

SUBSECTION II—Admission to medical schools and medical colleges in the association may be granted to candidates on the basis of examinations as hereinafter provided These examinations shall be conducted by such agencies as may be designated from time to time by the executive council of this association

(*a*) Candidates who have completed not less than 60 semester hours of collegiate instruction but who lack the full requirements in not more than two of the required subjects may be admitted on successfully passing examination in these subjects as provided above

A candidate to be examined under this section must give evidence of scholarship of high order.

(*b*) Candidates who have completed not less than 90 semester hours of collegiate instruction, but who lack credit in any or all of the required subjects, may be admitted on successfully passing examinations in these subjects as provided above

All candidates for the comprehensive examination must present evidence of having accomplished work of distinction in one or more fields of learning

The standards of instruction shall be as specified under subsection I

---

[1] A semester hour is the credit value of sixteen weeks' work, consisting of one lecture or recitation period per week, each period to be of not less than fifty minutes duration net At least two hours of laboratory work per week shall be necessary to be considered as the equivalent of one lecture or recitation period

[2] It is highly desirable that either the elements of physical chemistry be included in the course in general chemistry or presented as a supplementary course in the elementary physical chemistry

[3] It is recommended that additional work be offered in organic chemistry and that this additional work include a fair proportion of laboratory work

[4] In addition to the required course in general physics it is recommended that colleges provide an elective course suitable for students who desire more knowledge of physics than the general course affords and who expect to apply this knowledge to medicine and biology, rather than to engineering and physics

[5] In all cases the premedical biologic work should emphasize the great generalizations of biology—e g, the cell doctrine comparative anatomy and embryology recapitulation of phylogeny in ontogeny, adaptation to environment Special attention is called to the value of an elective second year course in general physiology in which a study is made of the application of physics and chemistry to life processes

> The cases have accordingly run to fine distinctions, and speaking for myself I doubt whether some dispositions in favor of animals held to be charitable under former decisions would be held charitable today. For instance, antivivisection societies, which were held to be charities by *Chitty J.* In re Foveaux (1895, 2 Ch. 501, 507), and were described by him as near the borderline, might possibly in the light of later knowledge in regard to the benefits accruing to mankind from vivisection be held not to be charities.

If the criterion by which the character of trusts is to be determined, in order to ascertain whether they are or are not charitable trusts, is the benefit that mankind will derive from them, it is difficult to see on what basis trusts for the hindrance or prevention of animal experimentation can be adjudged charitable. Certainly the weight of the evidence proves that animal experimentation is of benefit to mankind—and to animals, too, for that matter. If animal experimentation is for the benefit of mankind and of animals, bequests to hinder or prevent such experimentation obviously cannot be for the benefit of mankind, and bequests to accomplish that end cannot be charitable bequests. It may be argued that such reasoning is begging the question; that it assumes that the benefits that have been and are being derived from animal experimentation are at best not sufficient to offset the alleged cruelty of such experimentation. The answer is that there is no cruelty associated with animal experimentation that is not within the reach of the ordinary laws for the prevention of cruelty to animals. The fact that prosecutions for cruelty in connection with animal experimentation are practically unheard of, despite the vigilance of antivivisectionists, is evidence of the absence of such cruelty. The trouble with the antivivisectionists' reasoning lies in the fact that they fail to distinguish between pain and cruelty and set up their own standards of cruelty, which are not the standards of the law nor standards of the community.

From the decision of the Court of Appeal, an appeal was taken to the House of Lords. Apparently before a decision was reached there the contending parties had arrived at a compromise. The House of Lords therefore authorized the payment of £25,000, about $87,000, out of the residuary estate, to provide, in a manner approved by the proper court, for establishing and assisting homes or hospitals for animals, but on condition that no part of that sum should be available for antivivisection propaganda.

Probably these two decisions represent the general trend of mature and cultured thought on the subject of animal experimentation, when uninfluenced by lurid appeals to the imagination and by appeals to self interest. Both decisions were based on the orderly presentation of legal evidence, not on such clamorous, virulent, emotional speech-making as commonly fills the air when animal experimentation is discussed before legislative committees. If such committees would limit the presentation of evidence in the same way that it is limited by the courts, their decisions could be relied on to be as sound as the recent decisions of the U. S. Board of Tax Appeals and the English House of Lords and Court of Appeal. Doubtless, however, in the United States at least, the political aspects of hearings before legislative committees and the absence of well defined rules of evidence and procedure will continue too often to render orderly judgment impossible.

Current Comment

PREPAREDNESS FOR IMMUNIZATION

In most instances, oral administration of killed B. typhosus or of its lytic products fails to lead to the development of antibodies so far as can be determined. Nevertheless, Ruge[1] of the University of Kiel asserts that such oral vaccines are far from being ineffective. He claims that they lead to the development of a specific preparedness of the tissues, which is manifested by a more rapid and much more abundant production of antibodies on subsequent *subcutaneous* injection with the same vaccine. This specific preparedness, he believes, is in itself sufficient to insure relative personal safety under ordinary conditions of exposure. His data suggest a new technic for the clinical estimation of specific resistance, with numerous collateral applications in the study of allergy and of reciprocal bacterial relationships.

EXPERIMENTAL EVOLUTION OF BACTERIA

Many important advances in clinical medicine have followed the introduction of new or simplified laboratory technics, particularly such as yield dependable data in the hands of the average laboratory technician. A recently introduced method of this type, which may modify current conceptions of immunity, is the serial plating method of Hauduroy.[1] In a typical application of this method, Ryan and Arnold[2] of the University of Illinois were able to report the experimental evolution of certain "granules" in apparently sterile body fluids which passed through two or three intermediary stages to their final "transformation" into conventional bacteria or yeasts. The new serial plating method consists essentially in spreading an apparently sterile body fluid on the surface of nutrient agar or other solid culture medium. The "spread" is incubated two or three days, at the end of which time it shows no detectable microbic growth. Each "spread" is now "mopped up" with a small volume of nutrient broth and replanted on a fresh agar surface, the transplantations being repeated, if necessary, a dozen times. In the University of Illinois studies of apparently sterile stomach or duodenal smears after feeding Bacillus prodigiosus, the first demonstrable growth was not noted till the fifth serial transplant. The regenerated B. prodigiosus on this fifth plate appeared as a fusiform bacillus, "spindle-shaped rods with very slender tapering ends." Later transplants gave colonies with "an internal arrangement verified the status of the situation as related by Professor Penichet. In an account in his publication he pointed out its significance in relationship to conditions in this country. The medical profession of our own country certainly cannot anticipate better treatment or a more favorable consideration in relationship to some of the schemes now being exploited here. Certainly the Cuban medical profession has been but poorly rewarded for some fifty years of trial of such practice in that country. Inevitably, the physician who in times of stress disposes of his medical birthright as a professional man finds himself the drudge of the group that has purchased his scientific freedom. The physicians in Cuba who are the employees of the mutual aid societies work day and night for a pittance and are so constantly driven by the excessive demands on their services that they are unable to give to any patient the individual medical attention necessary to intelligent and satisfactory medical care. The rich patrons under these contracts no doubt demand and receive better service than is rendered to the membership generally. The old psychologic and biologic laws which communistic propagandists would invalidate in reforming medical care go right on working and eventually invalidate the experiments.

TRUSTS OPPOSING ANIMAL EXPERIMENTATION NOT CHARITABLE

Animal experimentation as a means of promoting human and animal welfare has recently received the sanction of two tribunals of great importance, one in the United States and the other in England. Both decisions tend to brighten the outlook for the protection of medical science against the perpetual warfare that threatens it through bequests for the support in perpetuity of organizations opposed to experiments on animals.

In the American case,[1] the United States Board of Tax Appeals held that a bequest to a society organized for "the total abolition of all vivisectional experiments on animals and other experiments of a painful nature" was not a bequest to a corporation organized and operated exclusively for the prevention of cruelty to animals, and that therefore the amount of such a bequest could not be deducted from the principal of an estate in computing the federal estate tax. The decision of the Court of Appeal in the English case[2] raised the question whether, "in the light of later knowledge in regard to the benefits accruing to mankind from vivisection," bequests designed to hinder and prevent vivisection would today be regarded as charitable bequests. On appeal, the House of Lords forbade the use for antivivisection propaganda of any part of the legacy concerning which the question was raised. The English decision is of only persuasive influence in the United States, but the changing view suggested by it with respect to bequests to create trusts to carry on activities against animal experimentation is of vital importance. Unless such trusts can be shown to be "charitable" in character, they cannot be made to operate in perpetuity.

The decision of the U. S. Board of Tax Appeals is printed at length in this issue.[3] It is a remarkable statement of the value of experimentation, all the more cogent because of the dispassionate, nonmedical, judicial source from which it emanated. The executor of the estate against whom the decision was rendered may appeal to the courts for relief, but a decision by an appellate court would almost certainly do nothing more than strengthen the defense of animal experimentation that the decision affords.

The English case arose out of a bequest of the residuary estate of the testatrix, amounting to about £200,000, or nearly $700,000 at the present rate of exchange, for an alleged charitable institution for the service of animals, all the officials of which should be and should always have been declared antivivisectionists. Hospitals and homes for animals were to be established, having no declared vivisectionists in any way connected with their management, and refuges were to be established where animals of all kinds should live free from molestation by man. The heir at law and the next of kin attacked the legality of the bequest. The trial court decided against them, and they appealed to the Court of Appeal. The Court of Appeal concluded, from authorities which it cited, that if a bequest was designed to secure good treatment for animals and to insure humane conduct toward them, whether in connection with vivisection or under other circumstances, it was a charitable bequest. It was charitable, however, not because it afforded protection to animals but because it stimulated humane and generous sentiments in man toward the lower animals and thus promoted feelings of humanity and morality generally, repressed cruelty, and elevated the human race. But because the proposed refuges for animals were to protect their occupants only from molestation and destruction by man and to leave every member of the brute creation within the so-called refuges to be the prey of every other creature, the purpose of the bequest seemed to the court to offer no protection from cruelty to animals generally and to denote no elevating lesson to mankind. The order of the court below, declaring the trust proposed by the will to be a valid trust, was therefore reversed.

Lord Justice Russel concurred in the decision of the court but filed a separate opinion in which he said:

> So far as I know there is no decision which upholds a trust in perpetuity in favor of animals upon any other ground than this, that the execution of the trust in the manner defined by the creator of the trust must produce some benefit to mankind. . . .

Glenn C. Blome, George H. Hansmann, Douglas H. Brown and Clark N. Cooper. Friday Drs. Peterson, Hansmann and Harold D. Kerr will lecture on general surgery and Dr. Jacob Kulowski and his staff will present a series on orthopedic surgery.

KENTUCKY

Changes Among Health Officers.—Appointments of new health officers have recently been made in several counties. Dr. Ollie M. Goodloe, Louisville, succeeds Dr. Sam R. Page in Breathitt County. Dr. Gradie R. Roundtree, Horse Cave, has been appointed in Adair County, and Dr. Charles Fred Blankenship, Hawesville, in Hancock County. Dr. Carl N. Gambill, Salyersville, is to succeed Dr. Miriam Marting, health officer of Greenup County, who recently resigned. Dr. Ernest M. Ewers, Somerset, has resigned in Pulaski County.

Society News. — The Sixth Councilor District Medical Society met in Lebanon, August 11. Among the speakers were Drs. Emmet F. Horine and Morris M. Weiss, Louisville, on "Congestive Heart Failure"; Curran Pope, Louisville, fever treatment, and Caswell C. Turner, Glasgow, roentgen diagnosis of pulmonary tuberculosis.——Dr. Amplias O. Sisk, Lexington, addressed the Bourbon County Medical Society, Paris, July 21, on tetanus and Dr. Charles G. Daugherty, treatment of typhoid.——Drs. Francis M. Massie and Donnan B. Harding, Lexington, addressed the Mason County Medical Association, at Maysville, August 10, on intestinal obstruction and roentgen diagnosis of gallbladder disease, respectively.

MARYLAND

Bone and Radiological Conference.—The Surgical Pathological Laboratory of Johns Hopkins Hospital, Baltimore, announces its annual conference on bone lesions and radiologic aspects of tumor diagnosis, to be held, September 19-24, under the direction of Drs. Joseph C. Bloodgood and Charles Geschickter. The first day of the conference will be devoted to work of interest to oral surgeons and others interested in the jaws, teeth and oral cavity. Tuesday there will be conferences on tumors of the jaw and giant cell tumors and Ewing's sarcoma. The main bone demonstration will occupy the last three days.

Typhoid on Freighter.—An outbreak of typhoid among the crew of the British steamship *Victoria City* was under investigation, August 6, by the Maryland State Department of Health, the New York *Sun* reported. Nine members of the crew were in University Hospital in Baltimore under treatment for typhoid, and two other sick seamen remained aboard the boat docked at quarantine station, Curtis Bay. When the most seriously ill of the crew was first taken to the hospital, the quarantine physician diagnosed the disease as typhoid. This diagnosis was confirmed at the hospital. The freighter left Nikoliadoff, Russia, July 7, took on water at Alexandria, Egypt, and stopped at Constanta, Rumania, before proceeding to Baltimore, the newspaper stated.

MICHIGAN

Seniors Win at Golf.—The Seniors, a group of Detroit physicians who have been in practice for twenty-five years or more, defeated the Noon Day Study Club, composed of doctors under the age of 40, in their first annual golf match at Meadowbrook, August 3. The match play ended in 28½ points in favor of the Seniors to the 22½ points for the Juniors. Seventeen matches were played. An additional fifteen Seniors arrived at the club but found no opponents among the Juniors.

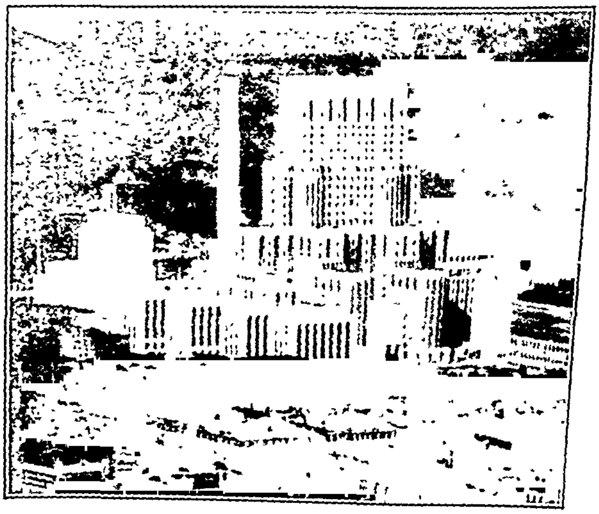
Personal.—Dr. Carl E. Badgley, Detroit, has been appointed assistant professor of surgery in the University of Michigan Medical School, Ann Arbor, succeeding Dr. Vernon L. Hart, who will be associated with the Dayton Clinic, Dayton, Ohio, October 1. Dr. Badgley, who had been associated with the university since 1919, resigned in 1929 to head the division of orthopedic surgery at Henry Ford Hospital. His appointment is effective, October 1.——Dr. Floyd J. Barkman, Calumet, has received the Order of the Purple Heart, for military merit during the World War.——Dr. Burt R. Shurly, Detroit, has been cited to receive the Order of the Purple Heart. The honor was ordered conferred for Dr. Shurly's service in the American Expeditionary Forces at base hospital number 36.——Dr. Eugene N. Nesbitt, Grand Rapids, has been appointed director of city welfare; he will continue his duties as superintendent of the city tuberculosis hospital.——Dr. Jay M. Burgess, Detroit, has been appointed coroner of Wayne County succeed his brother, the late Dr. James E. Burgess.

NEW YORK

Ordinance Against Fireworks.—Stimulated by an unusually high percentage of casualties from fireworks on the Fourth of July, the Common Council of Syracuse passed an ordinance, July 19, forbidding all display of fireworks except municipal displays under police supervision. The council was supported in its action by the Onondaga County Medical Society, the Syracuse Academy of Medicine, the Syracuse Eye, Ear, Nose and Throat Club and numerous civic organizations. The ordinance, which makes the use of fireworks punishable by a fine of not more than $150 or 150 days in jail, was passed without a dissenting vote. An amendment gives local dealers, who opposed the measure vigorously, until June 15, 1933, to dispose of their stocks.

New York City

New York Hospital-Cornell Medical Center to Open September 1.—The colossal plant of the New York Hospital-Cornell Medical College Association, which covers an area of three square blocks between Sixty-Eighth and Seventy-First streets overlooking the East River, will go into operation, September 1. The new medical center, which has been under construction since the fall of 1929, will consolidate three of New York's oldest hospitals and the Cornell University Medical College, making possible close coordination of university and hospital training for medical students. Dominating the closely connected buildings rises the central tower of the general hospital, twenty-seven stories high, opening on Sixty-Eighth Street. On the east along the river are three special hospitals One is the Women's Hospital, the successor of the old Lying-In Hospital and Manhattan Maternity Hospital. The second is a children's hospital and the third a psychiatric hospital, for which the late Payne Whitney made provision in his will. On the west of the main hospital building, along York Avenue, are the buildings of Cornell University Medical College. North of the hospital group are the nurses' residence and a building containing the power plant, service building, laundry, parking garage and, in the tower, an employees' dormitory. Accommodations are thus provided for 1,000 bed patients and approximately the same number of outpatients, 125 resident physicians, 500 nurses and 200 employees. Instruction will be provided for about 300 undergraduate medical students and for many advanced students. The main hospital is described as three buildings superimposed one on another. The general hospital forms the base of the structure, with two southern wings employed for the medical and surgical wards and two on the north side for the outpatient service and facilities for various types of treatment. Nineteen operating rooms fill the tenth and eleventh floors, separating the general from the private hospital. Above the private hospital are the living quarters for the resident staff. New York Hospital, the oldest in New York City and second oldest in the United States, wa formally opened in 1791 and was recognized as one of foremost schools of medicine and surgery. Students of Ki College were first to use its facilities; those of the Coll Physicians and Surgeons were instructed there from 1869. From 1866 to 1869 the medical college of Ne University was housed in the hospital. Since 191 funds given by the late George F. Baker, it has ith Cornell. The legacies of the late Payne



suggesting a tangled mass of threads." Faint pigment production was noted on the tenth serial plate. By the twelfth plate, B. prodigiosus had completed its ancestral evolutionary transformation into its usual present-day test-tube morphology. Somewhat similar primordeal fusiform and intermediary filamentous forms were noted in the ontogenic regeneration of yeasts. The fact that viable bacterial detritus can be demonstrated by the Hauduroy technic in otherwise sterile tissues, exudates and body fluids will probably produce much less certainty in diagnoses of "sterile abscesses," "aseptic inflammations" and local "allergic diseases."

Association News

MEDICAL BROADCAST FOR THE WEEK

American Medical Association Health Talks

The American Medical Association broadcasts on Monday and Wednesday from 10:45 to 10:50 a. m. over Station WBBM (770 kilocycles, or 389.4 meters). The Columbia chain program has been discontinued for the present.

The subjects for the week are as follows:

August 29.	The Old Oaken Bucket.
August 31.	The Father of Medicine.

There will be no broadcast, September 3, of the fifteen minute talk usually scheduled for Saturday morning at 10:45.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

Society News.—At a meeting of the Alameda County Medical Association in Oakland, August 15, the speakers were Drs. George F. Calvin, Oakland, on "Rôle of Endocrines in Uterine Hemorrhage"; William A. Clark, "Treatment of Uterine Displacement," and Edward N. Ewer, "Pelvic Inflammatory Diseases." J. F. Math, D.D.S., speaking for the dental profession, and Dr. Daniel Crosby, for the medical profession, gave a report of activities on modified cost in practice.——A Community Nursing Council was recently organized for Alameda County. Dr. Daniel Crosby, Oakland, is chairman.

Licenses Revoked.—At a meeting of the state board of medical examiners in San Francisco, July 14, the license to practice medicine of Dr. Carlos Hidalgo y Teran was revoked. Dr. Teran is now confined in the state narcotic hospital at Spadra, it is reported. The revocation of the license of Dr. Theodore H. Niemann, formerly of Los Angeles, at this meeting was based on narcotic derelictions. The board also revoked the license of Dr. Charles Bee Alexander, Alhambra; this action was based on his conviction of violation of the banking laws of the state of Washington. Dr. Alexander is now confined in the state penitentiary at Walla Walla, it is reported, having been sentenced, May 25, to "hard labor for the period of not less than one year and not more than fifteen years." Narcotic derelictions also caused the revocation of the license of Dr. John Theodore Kergan, Oakland, who is said to be an inmate of the state hospital at Spadra.

ILLINOIS

Personal.—Dr. and Mrs. Eli V. Rice, Polo, celebrated the golden anniversary of their wedding, August 8.——Dr. Samuel Reed Ward, Richmond, celebrated his ninetieth birthday, August 7, with a family reunion at Lauderdale Lake, near Elkhorn, Wis.

Chicago

Changes at University Medical Schools.—The following changes in the Division of Biological Sciences, University of Chicago and Rush Medical College, among others, are noted in the *University Record:*

APPOINTMENTS

Dr. Herbert E. Chamberlain, associate professor of psychiatry, department of pediatrics.
Dr. Oran I. Cutler, assistant professor, department of pathology.
Dr. Paul Oliver, assistant clinical professor, department of surgery, Rush Medical College.
Dr. Samuel Soskin, assistant professor, department of physiology.
Dr. David C. Straus, assistant clinical professor, department of surgery, Rush Medical College.
Dr. John M. Welch, assistant clinical professor of military medicine, department of medicine, Rush Medical College.
Dr. Agnes Beulah Cushman, clinical instructor, department of ophthalmology, Rush Medical College.
Dr. George Ormiston, instructor, department of pediatrics.
Dr. Gilbert Rich, clinical instructor in psychiatry, department of medicine, Rush Medical College.
Dr. Charles A. Sima, clinical instructor, department of medicine, Rush Medical College.

PROMOTIONS

Dr. Paul R. Cannon, to a professorship, department of pathology.
Dr. George M. Curtis, to a professorship, department of surgery.
Dr. Theodore Ticken, to a professorship emeritus, department of medicine, Rush Medical College.
Dr. George G. Davis, to an associate clinical professorship, department of surgery, Rush Medical College.
Dr. George E. Miller, to an associate clinical professorship (materia medica and toxicology), department of medicine, Rush Medical College.
Dr. James H. Mitchell, to an associate clinical professorship, department of dermatology, Rush Medical College.
Dr. Roger Throop Vaughan, to an associate clinical professorship, department of surgery, Rush Medical College.
Dr. Carl Philip Bauer, to an assistant clinical professorship, department of obstetrics and gynecology, Rush Medical College.
Dr. Morris Braude, to an assistant clinical professorship (psychiatry), department of medicine, Rush Medical College.
Dr. Douglas G. Campbell, to an assistant clinical professorship of psychiatry, department of medicine.
Dr. John A. Larson, to an assistant clinical professorship (psychiatry), department of medicine, Rush Medical College.
Dr. Richard B. Richter, to an assistant clinical professorship (neurology), department of medicine, Rush Medical College.
Dr. David B. Rotman, to an assistant clinical professorship (psychiatry), department of medicine, Rush Medical College.
Dr. George F. Dick, to chairmanship of department of medicine, Rush Medical College.
Dr. William F. Moncreiff, to chairmanship, department of ophthalmology, Rush Medical College.

RESIGNATIONS

Dr. Ludvig Hektoen as head of the department of pathology. He will continue as professor of pathology.
Dr. Earl B. Ritchie, as assistant professor of dermatology, department of medicine.

INDIANA

State Medical Meeting at Michigan City.—The Indiana State Medical Association will hold its eighty-third annual session at Michigan City, September 27-29, under the presidency of Dr. Franklin S. Crockett, La Fayette. Scientific sessions will begin Wednesday morning, September 28, with three sectional meetings at which courses of instruction will be given in "Mechanical Methods of Diagnosis," "Emergency Minor Surgery" and "Common Diseases of the Eye, Ear, Nose and Throat." Sections will also meet Thursday morning. Wednesday afternoon there will be a general scientific meeting and Thursday afternoon will be devoted to a general session on medical economics. Among speakers at the latter meeting will be Drs. Charles B. Wright, Minneapolis, on hospitalization of veterans and William C. Woodward, Chicago, director, Bureau of Legal Medicine and Legislation, American Medical Association, on "Legislation Before Congress of Interest to the Medical Profession." At the annual banquet, Thursday evening, Dr. Dean Lewis, Baltimore, president-elect of the American Medical Association, will give an address on "Changing Times in Medicine." A golf tournament will be held at the Long Beach Country Club Tuesday afternoon and the annual smoker will be held in the evening. The annual state health officers' conference will be held during this meeting, September 26-27.

IOWA

Annual Surgical Clinics.—Members of the faculty of the College of Medicine, State University of Iowa, Iowa City, will present the annual surgical survey course for physicians, arranged by the extension department, September 6-9. Tuesday will be devoted to gynecology under Dr. Everett D. Plass and his staff and to genito-urinary surgery under Dr. Nathaniel G. Alcock and his staff. Wednesday Dr. Dean M. Lierle and his staff will give instruction in otolaryngology and four surgeons in general surgery: Drs. Howard L. Beye, Frank R. Peterson, William H. Gibbon and Olan R. Hyndman. Thursday general surgery will be covered by Drs. Hyndman, Beye, the report said, accounting for 76 per cent of the 339 epidemics recorded in that time, 10,863, or 78 per cent, of the 14,266 cases and 424, or 94 per cent, of the 449 deaths. In Canada, four health officers reported four epidemics, involving 582 cases and 6 deaths during 1931. Paratyphoid B, scarlet fever and typhoid were the diseases included. One epidemic of paratyphoid B of 457 cases with 3 deaths was reported.

American Roentgen Ray Society.—The thirty-third annual meeting of the American Roentgen Ray Society will be held at the Book-Cadillac Hotel, Detroit, September 27-30. A consideration of pathology of the joints will occupy the first session. Wednesday morning will be devoted to a discussion of tuberculosis with special attention to its public health, diagnostic and therapeutic aspects, and the afternoon to uses of roentgenology in gynecology and obstetrics. Miscellaneous subjects will be considered, Thursday morning; the afternoon will be devoted to the question of roentgen and radium therapy. Speakers on the program will include Drs. Edwin A. Merritt, Washington, D. C., "Irradiation of the Parathyroids in Cystic Disease of the Bones"; Ralph S. Bromer, Philadelphia, "Osteogenesis Imperfecta"; Robert C. Moehlig, Detroit, "Pituitary Function as Related to Certain Conditions of the Uterus"; Henry J. Walton, Baltimore, "Roentgen Study as an Aid in Obstetrics," and Byrl R. Kirklin, Rochester, Minn., "Hypertrophy of the Pyloric Muscle and Duodenitis: Their Association and Roentgenologic Manifestations." Dr. Augustus W. Crane, Kalamazoo, will deliver the Caldwell Lecture, Wednesday evening.

PHILIPPINE ISLANDS

Society News.—The Manila Medical Society commemorated the fiftieth anniversary of the discovery of the tubercle bacillus with a special meeting, June 6, at which addresses were made, among others, by Drs. Carl M. Hasselmann, on "Robert Koch and His Work," and Antonio G. Sison, "Diagnosis of Pulmonary Tuberculosis."——Affiliation of the Occidental Negros Medical Association with the Philippine Islands Medical Association has recently been approved by the association council. Dr. Jose C. Locsin, Silay, is president.——Child Health Day was observed, June 19, by special designation of Governor General Roosevelt.

Medical School Celebrates Silver Jubilee.—The College of Medicine, University of the Philippines, observed the twenty-fifth anniversary of its founding with a banquet and special program at the School of Hygiene and Public Health, Manila, June 10. Dr. Jose Albert, chief of clinics, Philippine General Hospital, spoke on "Past and Future Achievements of the College of Medicine"; Dr. Sixto y Orosa, director, Bacolod Provincial Hospital, "Problems and Responsibilities of the Medical Profession," and Dr. Federico Delena, "The Present Medical Curriculum as Seen by a Young Graduate." Dr. Sixto de los Angeles, acting dean of the college, and Rafael Palma, LL.D., president of the university, also made addresses.

CANADA

University News.—The University of Alberta Faculty of Medicine conducted a five days' clinical course for physicians of the province at the University Hospital in May. It is expected that the course, the first of its kind at the university, will be continued and extended.

Personal.—Dr. Herbert S. Birkett, emeritus professor of otolaryngology, McGill University, was the guest of honor at a dinner given by his colleagues at the end of the school year. Dr. Birkett was graduated from McGill in 1886 and in 1887 began his association with the university as a demonstrator in anatomy. In 1894 he was made professor of laryngology and in 1906, professor of otolaryngology. During the World War he was in command of No. 3 Canadian General Hospital (McGill).——Dr. McGillivray S. Fraser, Winnipeg, chief health inspector of Manitoba for sixteen years, has retired from active service, having reached the age limit.

Institute for Study of Animal Parasites.—With the cooperation of the government of Quebec, the National Research Council and the Empire Marketing Board, an Institute of Animal Parasitology has recently been established at Macdonald College, McGill University, Montreal. Thomas Wright Moir Cameron, Ph.D., lecturer in helminthology at Edinburgh University, Scotland, has been chosen as director of the institute and research professor of animal parasitology, and Raymond L. Conklin, M.Sc., assistant professor of animal parasitology at McGill, will be associated with him in the development of the work. A new three story building with laboratory accommodations for a number of workers has been built for the institute.

Society News.—Dr. George A. B. Addy, St. John, N. B., was chosen president-elect of the Canadian Medical Association and Dr. Alexander Primrose, Toronto, became president at the annual meeting in Toronto in June. The next meeting will be held in St. John, June 19-23, 1933.——Dr. Charles C. Macklin, London, Ont., recently addressed the Ontario Laennec Society at Toronto, on "The Dynamic Bronchial Tree."——The annual meeting of the Alberta Medical Association will be held in Edmonton, September 20-22, under the presidency of Dr. Thomas W. E. Henry, Fort Saskatchewan.——Dr. Walter S. Turnbull, Vancouver, was made president-elect of the British Columbia Medical Association and Dr. William J. Knox, Kelowna, became president at the recent annual meeting.——The Manitoba Medical Association will hold its annual meeting in Winnipeg, September 8-10.——The first Empire Dental Convention was held in Toronto, August 8-12, when the British, Canadian and Ontario dental associations held joint sessions.

FOREIGN

Congress on Otorhinolaryngology.—At the Second International Congress on Otorhinolaryngology, which is to be held in Madrid, September 27-30, the subjects to be discussed are otosclerosis, ozena, scleroma, bronchoscopy and esophagoscopy, and treatment of malignant tumors by radium and roentgen rays. Among those who will participate in the program will be Drs. John Gordon Wilson, Chicago; Chevalier Jackson, Philadelphia; Otto Mayer, Vienna; Fernand Lemaitre, Paris; Ledoux, Brussels, and Barraud, Lausanne, Switzerland. The American delegation will sail, September 17, from New York on the S. S. *Rochambeau.* Information may be obtained from M. Marcel Colin, 8 Investment Building, Washington, D. C.

British Medical Election.—Dr. Thomas Gillman Moorhead, Dublin, president of the Royal College of Physicians of Ireland and regius professor of physic in Trinity College, University of Dublin, was chosen president-elect of the British Medical Association at the annual meeting in July in London. He will succeed Lord Dawson of Penn. It was announced that Dr. G. C. Anderson, deputy secretary of the association, would succeed Dr. Alfred Cox, who will retire, October 1. A portrait of Dr. Cox, painted by Sir Arthur Cope, was presented to the association at a special testimonial meeting. At the final general meeting a portrait of Dr. Elizabeth Garrett Anderson, first woman to be admitted to the association, was also presented. Dr. Leslie George Housden, Basingstoke, was announced as the winner of the Sir Charles Hastings Clinical Prize for 1932, for his essay entitled "Studies in Breast Feeding."

Society News.—Dr. Edgar D. Adrian gave the fourth Victor Horsley Memorial Lecture at the University College Hospital Medical School, London, July 20, on "The Visceral Sense Organs."——The West London Medico-Chirurgical Society celebrated its fiftieth anniversary at its annual dinner, July 8.——The third international congress of the International League Against Rheumatism will be held in Paris, October 13-15, under the presidency of Dr. R. Fortescue Fox, London. Subjects to be considered are early symptoms of chronic rheumatism, rheumatism and tuberculosis, rheumatism and the medical profession. Details may be obtained from Dr. J. Van Breemen, Keizersgracht 489, Amsterdam, or from Dr. Mathieu P. Weil, 60, Rue de Londres, Paris, IX.——Dr. John Shields Fairbairn, London, was recently elected president of the British College of Obstetricians and Gynecologists.——The seventh International Congress on the Care of Children will be held in Paris, July 5-9, 1933. Main subjects of discussion will be the medical supervision of sports and the relation between charity and the state.

Centenary of Irish Journal.—Two anniversaries are commemorated with the June issue of the *Irish Journal of Medical Science*—the centenary of the old *Dublin Journal of Medical Science* and the fiftieth anniversary of the founding of the Royal Academy of Medicine of Ireland, whose official organ the journal has become. In 1832, Robert John Kane began the publication of the *Dublin Journal of Medical and Chemical Science.* With the issue of May, 1836, the name was changed to the *Dublin Journal of Medical Science.* In 1845 the series was brought to a close and on Feb. 1, 1846, appeared the first number of the *Dublin Quarterly Journal of Medical Science.* The Royal Academy of Medicine, which had been founded in 1882, assumed full control of the journal in March, 1920. The centenary issue opens and closes with articles by Dr. Thomas P. C. Kirkpatrick, secretary general, Royal Academy of Medicine in Ireland. It contains papers by Dr. George Crile, Cleveland; Sir Humphry Rolleston, Sir Robert Jones, E. Hastings Tweedy, J. M. Munro Kerr, Jean-Louis Faure and E. Essen-Möller.

opened the way for its recent advances. The first building of the hospital, occupied for nearly a century, was on Broadway near Duane Street. In 1877 it moved to West Sixteenth Street near Fifth Avenue, from which it has moved to the new site. The hospital staff is now organized in five divisions: medicine, surgery, gynecology and obstetrics, pediatrics and psychiatry. All medical teaching that has to do directly with treatment of patients will be conducted by members of the staff, who will also hold appointments in the medical school faculty. Departmental chiefs will be on a full-time basis, though numerically the major portion of the staff will be composed of physicians also engaged in private practice. The New York Hospital-Cornell University project has been completed under the direction of a joint administrative board, of which the chairman is Edward W. Sheldon and the members are Frank L. Polk, William Woodward, Dr. Livingston Farrand, J. Du Pratt White, Dr. Walter L. Niles and J. Pierpont Morgan. Dr. G. Canby Robinson is the executive officer in charge.

PENNSYLVANIA

Society News.—Drs. Ferd E. Weddigen, Williamsport, and Thomas McKean Downs, Philadelphia, addressed the Lycoming County Medical Society in July on "The Friedman Modification of the Aschheim-Zondek Test for Early Pregnancy" and "Tannic Acid Treatment of Burns," respectively.——The Westmoreland County Medical Society held its annual welfare meeting at the Torrance State Hospital, August 23. Dr. Cornelius C. Wholey, Pittsburgh, reported a case of multiple personality, with motion pictures; Drs. Josephine Funderburgh and Theodore Wollak of the hospital staff discussed treatment of dementia paralytica with malaria and complications of arsenical medication, respectively.

Philadelphia

Appointments at Temple.—New appointments to the faculty of Temple University School of Medicine recently announced by Dr. William N. Parkinson, dean, include:

Dr. Ralph M. Tyson, professor of pediatrics.

Drs. William Henry Crawford, Edward D. Atlee and James Edward Bowman, instructors in pediatrics.

Dr. Henry H. Perlman, demonstrator in pediatrics.

Drs. Scott P. Verrei, Joseph Levitsky, Robert S. Heffner and Paul B. Bender, clinical assistants in pediatrics.

Dr. Nicholas Gotten, lecturer in neurosurgery.

Hugo Roesler, Ph.D, has been promoted to the rank of associate professor of radiology.

RHODE ISLAND

State Psychiatrist Appointed.—Dr. George M. Lott, Denver, formerly connected with the Institute of Child Guidance, New York, has been appointed psychiatrist to state institutions of Rhode Island, a full time position created by the last general assembly, according to newspaper reports. Dr. Lott will begin work, September 1, as psychiatrist to the state penal institutions and chief of staff of the psychiatric clinic serving the probation department and the children's bureau. He may also be called on by the attorney general to examine criminals. Dr. Lott is a graduate of the University of Colorado, class of 1928, and has served on the staff of the Boston Psychopathic Hospital and the Cornell Clinic in New York, in addition to the Institute for Child Guidance. Psychiatric work had previously been performed by Dr. John E. Donley, Providence, on a part time basis.

SOUTH CAROLINA

Society News.—At a meeting of the Pickens County Medical Society at the home of Dr. John L. Valley, Pickens, July 6, Dr. James R. Young, Anderson, president of the South Carolina Medical Association, discussed the problem of accidents with relation to hospitals, and Drs. Edgar A. Hines, Seneca, Thaddeus B. Reeves, Greenville, and Howard Anthony, Anderson, government hospitalization of veterans. Dr. Ernest W. Carpenter, Greenville, discussed arthritis and Dr. William A. Sheldon, Liberty, presented a case of tumor of the right hypochondrium.——Dr. William R. Barron, Columbia, addressed the Ridge Medical Society, Edgefield, recently, on surgery of the prostate.

UTAH

License Revocations.—Dr. George W. Baker, Ogden, who appealed to the state supreme court from an order issued by the state department of registration in October, 1931, revoking his license to practice, surrendered the license, July 29, after his case had been referred to the district court. The original order of revocation thereupon became effective. He was charged with performing an abortion. The license of Ben E. Mason, a chiropractor, was revoked in April on a charge of professing publicly to treat human ailments under a system or school of treatment or practice other than that for which he was licensed.

WISCONSIN

State Medical Meeting at Milwaukee.—The ninety-first annual meeting of the State Medical Society of Wisconsin will be held in Milwaukee, September 14-16, with headquarters at the Schroeder Hotel. Dr. George W. Crile, Cleveland, will give the annual oration in surgery, on "Denervation of the Adrenal Glands"; Dr. David P. Barr, St. Louis, will give the oration in medicine, on "The Parathyroid Glands and Their Relation to Calcium Metabolism." At the annual dinner, Thursday evening, September 15, Richard E. Scammon, Ph.D., Minneapolis, will be the speaker, on "The Foundation and Early History of St. Bartholomew's—the First Hospital in London." Guest speakers who will take part in the program include:

Dr. Max Cutler, Chicago, on "Clinical and Pathological Aspects of the Cancer Problem."

Dr. Udo J. Wile, Ann Arbor, Mich., "Occult Syphilis: A Neglected Factor in Diagnosis and Treatment."

Dr. Elexious T. Bell, Minneapolis, "Etiology and Pathology of Nephritis."

Dr. William W. Duke, Kansas City, "Dawn of a New Specialty in Medicine: Allergy."

Dr. Samuel Amberg, Rochester, Minn., "Observations on Some Abdominal Conditions in Childhood."

Dr. John W. Towey, Powers, Mich., "The Effect on the Lungs of Fungus Spores Found in Maple Bark."

Dr. Charles H. Watkins, Rochester, Minn., "Leukopenia and Acute Leukemias with the Differential Diagnosis from Similar Blood Conditions."

Dr. Elsworth S. Smith, St. Louis, "Treatment of Heart Disease."

Dr. Julius Bauer, Vienna, Austria, "Constitutional Factors in Disease."

The annual golf tournament will be held at the Tripoli Country Club, Tuesday, September 13. Clinics and demonstrations will be held in ten Milwaukee hospitals, Wednesday morning.

GENERAL

New Pediatric Journal.—Two issues have appeared of the new organ of the American Academy of Pediatrics, called the *Journal of Pediatrics.* Drs. Borden S. Veeder and Hugh McCulloch, St. Louis, are editors. The journal contains original articles, book reviews, editorials and the proceedings of the recent meeting of the academy.

Society News.—Officers elected at the meeting of the Pacific Coast Oto-Ophthalmological Society in Seattle, June 30-July 2, were Drs. Hans Barkan, San Francisco, president; Bertram C. Davies, Los Angeles, and Leo B. Bouvy, La Grande, Ore., vice president, and J. Frank Friesen, Los Angeles, secretary.——The Association of Military Surgeons of the United States recently presented to the Association of Military Surgeons of Mexico a bronze plaque as a token of friendship and good will. In recognition of the Washington bicentennial year, the plaque bears a profile of Washington. Lieut. Col. William Lee Hart and Col. Percy M. Ashburn, Medical Corps, U. S. Army, made the presentation at a session of the Mexican society in Mexico City, May 30.——National Pharmacy Week will be observed, October 10-15.

Deaths in 1930.—There were 1,343,356 deaths reported in the United States death registration area in 1930, with a rate of 1,133.1 per hundred thousand of population, according to statistics just made public by the U. S. Department of Commerce. Deaths and rate for 1929 were 1,386,363 and 1,191.9, respectively. The decrease was caused almost entirely by a reduction in the number of deaths from influenza from 64,853 in 1929 to 23,066 in 1930 and in those from pneumonia from 106,597 to 98,657. Whooping cough and diphtheria also decreased about 2,000 deaths each. Diseases of the heart and cancer showed the only significant increases. Heart diseases caused 253,084 deaths in 1930, compared with 245,244 in 1929, and the respective rates were 213.5 and 210.8 per hundred thousand. Deaths from cancer and other malignant diseases increased from 111,569 in 1929 to 115,265 in 1930 and the rate from 95.9 to 97.2. There were 29,080 deaths from automobile accidents exclusive of collisions with railroad trains (1,760) and street cars (463).

Milk-Borne Epidemic Diseases.—Nineteen state health officers reported thirty-seven milk-borne epidemics in the United States during 1931, according to the *Child Health Bulletin.* In this total, 1,383 cases and 22 deaths were involved. The diseases believed to have been spread by milk were bacillary dysentery, diphtheria, diarrhea, food poisoning, gastro-enteritis, paratyphoid, poliomyelitis, scarlet fever, septic sore throat, typhoid fever and undulant fever. Typhoid was the cause of eighteen of the thirty-seven epidemics. Septic sore throat, with nine outbreaks, was second. These two diseases were responsible for 73 per cent of the epidemics, 1,168, or 84 per cent, of the cases and 22, or 100 per cent, of the deaths. They occupied a similar position continuously in the last eight years.

are milk, butter, egg yolk and the fat of meat and fish. All these contain vitamin D, and of these milk, cheese and egg yolk are also rich in calcium and phosphorus. The chief foods hindering calcification are cereals—bread, oatmeal, maize, rice. Other foods which, by stimulating growth and not exerting a corresponding influence on calcification, tend to bring about defective bone formation include lean meat, white fish and most vegetable fats. Vegetables and fruit seem to be more or less indifferent in their action, although in some circumstances the calcium content, especially in the case of green vegetables, may aid calcification. Sometimes green vegetables may even contain a small amount of vitamin D, especially if recently exposed to sunlight. Naturally, also, the vitamin C content of fruit and vegetables prevents scurvy, and thus defends the bones against scorbutic influences. Thus the need for including calcifying foods in the diet is greatest during growth and when cereals are the main constituents of the diet. Since the child's consumption of food is limited, the greater the amount of bread and other cereals eaten the less likely is it that sufficient milk and eggs will be consumed to insure proper bone formation. Further, cereals are the cheapest and therefore the most greatly consumed articles of diet. Climatic conditions in this country are such that the baneful effects of cereals cannot ordinarily be counteracted by ultraviolet radiations. Indeed, all the circumstances—climatic, dietetic and economic—in this country appear to be conducive to defective bone formation. No cereal concoction or cereals ought to be given to an infant for the first eight or nine months, and even after this only in small amounts for the first two years. Cereals form far too great a part of the diet at all ages and might well be replaced to a large extent by milk, eggs, cheese, vegetables and fruit throughout life. The high cost of milk makes a sufficiency difficult for a large proportion of the population; large scale reduction of rickets by increased consumption of milk is therefore unlikely at present. Nor will butter act as a substitute for milk, since in the presence of cereals the antirachitic action of butter is small. But butter can be made much more antirachitic by giving it with additional calcium, 10 per cent calcium phosphate or carbonate. If some means could be found of making butter so that it retained the calcium of the milk, a great advance in the improvement of bone formation would follow.
